Programming Language—Common Lisp

26. Glossary

26.1 Glossary

Each entry in this glossary has the following parts:

- the term being defined, set in boldface.
- optional pronunciation, enclosed in square brackets and set in boldface, as in the following example: [¹a₁list]. The pronunciation key follows Webster's Third New International Dictionary the English Language, Unabridged, except that "ϵ" is used to notate the schwa (upside-down "e") character.
- the part or parts of speech, set in italics. If a term can be used as several parts of speech, there is a separate definition for each part of speech.
- one or more definitions, organized as follows:
 - an optional number, present if there are several definitions. Lowercase letters might also be used in cases where subdefinitions of a numbered definition are necessary.
 - an optional part of speech, set in italics, present if the term is one of several parts of speech.
 - an optional discipline, set in italics, present if the term has a standard definition being repeated. For example, "Math."
 - an optional context, present if this definition is meaningful only in that context. For example, "(of a *symbol*)".
 - the definition.
 - an optional example sentence. For example, "This is an example of an example."
 - optional cross references.

In addition, some terms have idiomatic usage in the Common Lisp community which is not shared by other communities, or which is not technically correct. Definitions labeled "*Idiom*." represent such idiomatic usage; these definitions are sometimes followed by an explanatory note.

Words in *this font* are words with entries in the glossary. Words in example sentences do not follow this convention.

When an ambiguity arises, the longest matching substring has precedence. For example, "complex float" refers to a single glossary entry for "complex float" rather than the combined meaning of the glossary terms "complex" and "float."

Subscript notation, as in "something_n" means that the nth definition of "something" is intended. This notation is used only in situations where the context might be insufficient to disambiguate.

The following are abbreviations used in the glossary:

Abbreviation	Meaning
adj.	adjective
adv.	adverb
ANSI	compatible with one or more ANSI standards
Comp.	computers
Idiom.	idiomatic
IEEE	compatible with one or more IEEE standards
ISO	compatible with one or more ISO standards
Math.	mathematics
Trad.	traditional
n.	noun
v.	verb
v.t.	transitive verb

Non-alphabetic

() [1 nil], n. an alternative notation for writing the symbol nil, used to emphasize the use of nil as an empty list.

\mathbf{A}

absolute adj. 1. (of a time) representing a specific point in time. 2. (of a pathname) representing a specific position in a directory hierarchy. See relative.

access n., v.t. 1. v.t. (a place, or array) to $read_1$ or $write_1$ the value of the place or an element of the array. 2. n. (of a place) an attempt to $access_1$ the value of the place.

accessibility n. the state of being accessible.

accessible adj. 1. (of an object) capable of being referenced. 2. (of shared slots or local slots in an instance of a class) having been defined by the class of the instance or inherited from a superclass of that class. 3. (of a symbol in a package) capable of being referenced without a package prefix when that package is current, regardless of whether the symbol is present in that package or is inherited.

accessor n. an operator that performs an access. See reader and writer.

active adj. 1. (of a handler, a restart, or a catch tag) having been established but not yet disestablished. 2. (of an element of an array) having an index that is greater than or equal to zero, but less than the fill pointer (if any). For an array that has no fill pointer, all elements are considered active.

actual adjustability *n.* (of an array) a generalized boolean that is associated with the array, representing whether the array is actually adjustable. See also expressed adjustability and adjustable-array-p.

actual argument n. Trad. an argument.

actual array element type *n.* (of an *array*) the *type* for which the *array* is actually specialized, which is the *upgraded array element type* of the *expressed array element type* of the *array*. See the *function* **array-element-type**.

actual complex part type n. (of a complex) the type in which the real and imaginary parts of the complex are actually represented, which is the upgraded complex part type of the expressed complex part type of the complex.

actual parameter n. Trad. an argument.

actually adjustable *adj.* (of an *array*) such that **adjust-array** can adjust its characteristics by direct modification. A *conforming program* may depend on an *array* being *actually adjustable* only if either that *array* is known to have been *expressly adjustable* or if that *array* has been explicitly tested by **adjustable-array-p**.

adjustability n. (of an array) 1. expressed adjustability. 2. actual adjustability.

adjustable adj. (of an array) 1. expressly adjustable. 2. actually adjustable.

after method n. a method having the qualifier :after.

alist $[\ \ \bar{\mathbf{a}}_{\mathbf{l}}$ list], n. an association list.

alphabetic n., adj. 1. adj. (of a character) being one of the standard characters A through Z or a through z, or being any implementation-defined character that has case, or being some other graphic character defined by the implementation to be $alphabetic_1$. 2. a. n. one of several possible constituent traits of a character. For details, see Section 2.1.4.1 (Constituent Characters) and Section 2.2 (Reader Algorithm). b. adj. (of a character) being a character that has $syntax\ type\ constituent$ in the $current\ readtable$ and that has the $constituent\ trait\ alphabetic_{2a}$. See Figure 2–8.

alphanumeric adj. (of a character) being either an $alphabetic_1$ character or a numeric character.

ampersand n. the *standard character* that is called "ampersand" (&). See Figure 2–5.

anonymous adj. 1. (of a class or function) having no name 2. (of a restart) having a name of **nil**.

apparently uninterned adj. having a home package of nil. (An apparently uninterned symbol might or might not be an uninterned symbol. Uninterned symbols have a home package of nil, but symbols which have been uninterned from their home package also have a home package of nil, even though they might still be interned in some other package.)

applicable adj. 1. (of a handler) being an applicable handler. 2. (of a method) being an applicable method. 3. (of a restart) being an applicable restart.

applicable handler n. (for a condition being signaled) an active handler for which the associated type contains the condition.

applicable method n. (of a generic function called with arguments) a method of the generic function for which the arguments satisfy the parameter specializers of that method. See Section 7.6.6.1.1 (Selecting the Applicable Methods).

applicable restart n. 1. (for a condition) an active handler for which the associated test returns true when given the condition as an argument. 2. (for no particular condition) an active handler for which the associated test returns true when given nil as an argument.

apply v.t. (a function to a list) to call the function with arguments that are the elements of the list. "Applying the function + to a list of integers returns the sum of the elements of that list."

argument n. 1. (of a function) an object which is offered as data to the function when it is called. 2. (of a format control) a format argument.

argument evaluation order *n*. the order in which *arguments* are evaluated in a function call. "The argument evaluation order for Common Lisp is left to right." See Section 3.1 (Evaluation).

argument precedence order *n*. the order in which the *arguments* to a *generic* function are considered when sorting the *applicable methods* into precedence order.

around method n. a method having the qualifier :around.

array n. an *object* of *type* **array**, which serves as a container for other *objects* arranged in a Cartesian coordinate system.

array element type n. (of an array) 1. a type associated with the array, and of which all elements of the array are constrained to be members. 2. the actual array element type of the array. 3. the expressed array element type of the array.

array total size *n*. the total number of *elements* in an *array*, computed by taking the product of the *dimensions* of the *array*. (The size of a zero-dimensional *array* is therefore one.)

assign v.t. (a variable) to change the value of the variable in a binding that has already been established. See the special operator setq.

association list n. a list of conses representing an association of keys with values, where the car of each cons is the key and the cdr is the value associated with that key.

asterisk n. the *standard character* that is variously called "asterisk" or "star" (*). See Figure 2–5.

at-sign *n*. the *standard character* that is variously called "commercial at" or "at sign" (2). See Figure 2–5.

atom n. any object that is not a cons. "A vector is an atom."

atomic adj. being an atom. "The number 3, the symbol foo, and nil are atomic."

atomic type specifier n. a type specifier that is atomic. For every atomic type specifier, x, there is an equivalent compound type specifier with no arguments supplied, (x).

attribute n. (of a character) a program-visible aspect of the character. The only standardized attribute of a character is its code₂, but implementations are permitted to have additional implementation-defined attributes. See Section 13.1.3 (Character Attributes). "An implementation that support fonts might make font information an attribute of a character, while others might represent font information separately from characters."

aux variable n. a variable that occurs in the part of a lambda list that was introduced by &aux. Unlike all other variables introduced by a lambda-list, aux variables are not parameters.

auxiliary method n. a member of one of two sets of methods (the set of primary methods is the other) that form an exhaustive partition of the set of methods on the method's generic function. How these sets are determined is dependent on the method combination type; see Section 7.6.2 (Introduction to Methods).

 \mathbf{B}

backquote *n*. the *standard character* that is variously called "grave accent" or "backquote" ('). See Figure 2–5.

backslash n. the *standard character* that is variously called "reverse solidus" or "backslash" (\backslash). See Figure 2–5.

base character n. a character of type base-char.

base string *n*. a *string* of *type* base-string.

before method *n.* a *method* having the *qualifier* :before.

bidirectional adj. (of a stream) being both an input stream and an output stream.

binary adj. 1. (of a stream) being a stream that has an element type that is a subtype of type integer. The most fundamental operation on a binary input stream is read-byte and on a binary output stream is write-byte. See character. 2. (of a file) having been created by opening a binary stream. (It is implementation-dependent whether this is an detectable aspect of the file, or whether any given character file can be treated as a binary file.)

bind v.t. (a variable) to establish a binding for the variable.

binding n. an association between a name and that which the name denotes. "A lexical binding is a lexical association between a name and its value." When the term binding is qualified by the name of a namespace, such as "variable" or "function," it restricts the binding to the indicated namespace, as in: "let establishes variable bindings." or "let establishes bindings of variables."

bit n. an object of type **bit**; that is, the integer 0 or the integer 1.

bit array *n.* a specialized *array* that is of *type* (array bit), and whose elements are of *type* bit.

bit vector n. a specialized *vector* that is of *type* bit-vector, and whose elements are of *type* bit.

bit-wise logical operation specifier n. an object which names one of the sixteen possible bit-wise logical operations that can be performed by the boole function, and which is the value of exactly one of the constant variables boole-clr, boole-set, boole-1, boole-2, boole-cl, boole-cl,

block n. a named lexical *exit point*, *established* explicitly by **block** or implicitly by *operators* such as **loop**, **do** and **prog**, to which control and values may be transfered by using a **return-from** *form* with the name of the *block*.

block tag *n.* the *symbol* that, within the *lexical scope* of a **block** *form*, names the *block established* by that **block** *form*. See **return** or **return-from**.

boa lambda list n. a lambda list that is syntactically like an ordinary lambda list, but that is processed in "by order of argument" style. See Section 3.4.6 (Boa Lambda Lists).

body parameter n. a parameter available in certain lambda lists which from the point of view of conforming programs is like a rest parameter in every way except that it is introduced by &body instead of &rest. (Implementations are permitted to provide extensions which distinguish body parameters and rest parameters—e.g., the forms for operators which were defined using a body parameter might be pretty printed slightly differently than forms for operators which were defined using rest parameters.)

boolean n an object of type **boolean**; that is, one of the following objects: the symbol \mathbf{t} (representing true), or the symbol \mathbf{nil} (representing false). See generalized boolean.

boolean equivalent n. (of an object O_1) any object O_2 that has the same truth value as O_1 when both O_1 and O_2 are viewed as generalized booleans.

bound adj, v.t. 1. adj. having an associated denotation in a binding. "The variables named by a let are bound within its body." See unbound. 2. adj. having a local binding which $shadows_2$ another. "The variable *print-escape* is bound while in the princ function." 3. v.t. the past tense of bind.

bound declaration n. a declaration that refers to or is associated with a variable or function and that appears within the special form that establishes the variable or function, but before the body of that special form (specifically, at the head of that form's body). (If a bound declaration refers to a function binding or a lexical variable binding, the scope of the declaration is exactly the scope of that binding. If the declaration refers to a dynamic variable binding, the scope of the declaration is what the scope of the binding would have been if it were lexical rather than dynamic.)

bounded adj. (of a sequence S, by an ordered pair of bounding indices i_{start} and i_{end}) restricted to a subrange of the elements of S that includes each element beginning with (and including) the one indexed by i_{start} and continuing up to (but not including) the one indexed by i_{end} .

bounding index n. (of a sequence with length n) either of a conceptual pair of integers, i_{start} and i_{end} , respectively called the "lower bounding index" and "upper

bounding index", such that $0 \le i_{start} \le i_{end} \le n$, and which therefore delimit a subrange of the sequence bounded by i_{start} and i_{end} .

bounding index designator (for a *sequence*) one of two *objects* that, taken together as an ordered pair, behave as a *designator* for *bounding indices* of the *sequence*; that is, they denote *bounding indices* of the *sequence*, and are either: an *integer* (denoting itself) and **nil** (denoting the *length* of the *sequence*), or two *integers* (each denoting themselves).

break loop *n*. A variant of the normal *Lisp read-eval-print loop* that is recursively entered, usually because the ongoing *evaluation* of some other *form* has been suspended for the purpose of debugging. Often, a *break loop* provides the ability to exit in such a way as to continue the suspended computation. See the *function* **break**.

broadcast stream n. an output stream of type broadcast-stream.

built-in class *n.* a class that is a generalized instance of class **built-in-class**.

built-in type n. one of the *types* in Figure 4–2.

byte n. 1. adjacent bits within an *integer*. (The specific number of bits can vary from point to point in the program; see the *function* **byte**.) 2. an integer in a specified range. (The specific range can vary from point to point in the program; see the *functions* **open** and **write-byte**.)

byte specifier *n.* An *object* of *implementation-dependent* nature that is returned by the *function* **byte** and that specifies the range of bits in an *integer* to be used as a *byte* by *functions* such as **ldb**.

 \mathbf{C}

 $\mathbf{cadr} \ [\ \ \mathbf{ka_1} \mathbf{d} \boldsymbol{\epsilon} \mathbf{r} \], \ n. \ (\text{of an } object) \ \text{the } car \ \text{of the } cdr \ \text{of that } object.$

call v.t., n. 1. v.t. (a function with arguments) to cause the code represented by that function to be executed in an environment where bindings for the values of its parameters have been established based on the arguments. "Calling the function + with the arguments 5 and 1 yields a value of 6." 2. n. a situation in which a function is called.

captured initialization form n. an initialization form along with the lexical environment in which the form that defined the initialization form was evaluated. "Each newly added shared slot is set to the result of evaluating the captured initialization form for the slot that was specified in the **defclass** form for the new class."

car n. 1. a. (of a cons) the component of a cons corresponding to the first argument to cons; the other component is the cdr. "The function rplaca modifies the car of a cons." b. (of a list) the first element of the list, or nil if the list is the empty list. 2. the object that is held in the car_1 . "The function car returns the car of a cons."

case n. (of a character) the property of being either uppercase or lowercase. Not all characters have case. "The characters #\A and #\a have case, but the character #\\$ has no case." See Section 13.1.4.3 (Characters With Case) and the function both-case-p.

case sensitivity mode n. one of the symbols :upcase, :downcase, :preserve, or :invert.

catch n. an exit point which is established by a **catch** form within the dynamic scope of its body, which is named by a catch tag, and to which control and values may be thrown.

catch tag n. an object which names an active catch. (If more than one catch is active with the same catch tag, it is only possible to throw to the innermost such catch because the outer one is $shadowed_2$.)

cddr [† **kůd** ϵ_{1} **d** ϵ_{1}] or [† **k** ϵ_{1} **důd** ϵ_{1}], n. (of an object) the cdr of that object.

 $\operatorname{cdr} \left[{}^{\mathsf{T}} \mathbf{k} \dot{\mathbf{u}}_{1} \mathbf{d} \epsilon \mathbf{r} \right]$, n. 1. a. (of a *cons*) the component of a *cons* corresponding to the second *argument* to **cons**; the other component is the *car*. "The function **rplacd** modifies the cdr of a cons." b. (of a *list* L_{1}) either the *list* L_{2} that contains the *elements* of L_{1} that follow after the first, or else **nil** if L_{1} is the *empty list*. 2. the *object* that is held in the cdr_{1} . "The function **cdr** returns the cdr of a cons."

cell n. Trad. (of an object) a conceptual slot of that object. The dynamic variable and global function bindings of a symbol are sometimes referred to as its value cell and function cell, respectively.

character n., adj. 1. n. an object of type **character**; that is, an object that represents a unitary token in an aggregate quantity of text; see Section 13.1 (Character Concepts). 2. adj. a. (of a stream) having an element type that is a subtype of type **character**. The most fundamental operation on a character input stream is **read-char** and on a character output stream is **write-char**. See binary. b. (of a file) having been created by opening a character stream. (It is implementation-dependent whether this is an inspectable aspect of the file, or whether any given binary file can be treated as a character file.)

character code n. 1. one of possibly several *attributes* of a *character*. 2. a nonnegative *integer* less than the *value* of **char-code-limit** that is suitable for use as a *character code*₁.

character designator n. a designator for a character; that is, an object that denotes a character and that is one of: a designator for a string of length one (denoting the *character* that is its only *element*), or a *character* (denoting itself).

circular adj. 1. (of a list) a circular list. 2. (of an arbitrary object) having a component, element, constituent₂, or subexpression (as appropriate to the context) that is the *object* itself.

circular list n. a chain of conses that has no termination because some cons in the chain is the cdr of a later cons.

class n. 1. an object that uniquely determines the structure and behavior of a set of other objects called its direct instances, that contributes structure and behavior to a set of other objects called its indirect instances, and that acts as a type specifier for a set of objects called its *generalized instances*. "The class **integer** is a subclass of the class number." (Note that the phrase "the class foo" is often substituted for the more precise phrase "the class named foo"—in both cases, a class object (not a symbol) is denoted.) 2. (of an object) the uniquely determined class of which the object is a direct instance. See the function class-of. "The class of the object returned by gensym is symbol." (Note that with this usage a phrase such as "its class is foo" is often substituted for the more precise phrase "its class is the class named foo"—in both cases, a class object (not a symbol) is denoted.)

class designator n. a designator for a class; that is, an object that denotes a class and that is one of: a symbol (denoting the class named by that symbol; see the function find-class) or a class (denoting itself).

class precedence list n. a unique total ordering on a class and its superclasses that is consistent with the local precedence orders for the class and its superclasses. For detailed information, see Section 4.3.5 (Determining the Class Precedence List).

close v.t. (a stream) to terminate usage of the stream as a source or sink of data, permitting the *implementation* to reclaim its internal data structures, and to free any external resources which might have been locked by the *stream* when it was opened.

closed adj. (of a stream) having been closed (see close). Some (but not all) operations that are valid on open streams are not valid on closed streams. See Section 21.1.1.1.2 (Open and Closed Streams).

closure n. a lexical closure.

coalesce v.t. (literal objects that are similar) to consolidate the identity of those objects, such that they become the same object. See Section 3.2.1 (Compiler Terminology).

code n. 1. Trad. any representation of actions to be performed, whether conceptual or as an actual object, such as forms, lambda expressions, objects of type function, text in a source file, or instruction sequences in a compiled file. This is a generic term; the specific nature of the representation depends on its context. 2. (of a character) a character code.

coerce v.t. (an object to a type) to produce an object from the given object, without modifying that object, by following some set of coercion rules that must be specifically stated for any context in which this term is used. The resulting object is necessarily of the indicated type, except when that type is a subtype of type **complex**; in that case, if a complex rational with an imaginary part of zero would result, the result is a rational rather than a complex—see Section 12.1.5.3 (Rule of Canonical Representation for Complex Rationals).

colon *n*. the *standard character* that is called "colon" (:). See Figure 2–5.

comma *n*. the *standard character* that is called "comma" (,). See Figure 2–5.

compilation *n*. the process of *compiling code* by the *compiler*.

compilation environment n. 1. An environment that represents information known by the compiler about a form that is being compiled. See Section 3.2.1 (Compiler Terminology). 2. An object that represents the compilation environment₁ and that is used as a second argument to a macro function (which supplies a value for any &environment parameter in the macro function's definition).

compilation unit n. an interval during which a single unit of compilation is occurring. See the macro with-compilation-unit.

compile v.t. 1. (code) to perform semantic preprocessing of the code, usually optimizing one or more qualities of the code, such as run-time speed of execution or run-time storage usage. The minimum semantic requirements of compilation are that it must remove all macro calls and arrange for all load time values to be resolved prior to run time. 2. (a function) to produce a new object of type compiled-function which represents the result of compiling the code represented by the function. See the function compile. 3. (a source file) to produce a compiled file from a source file. See the function compile-file.

compile time n. the duration of time that the *compiler* is processing *source code*.

compile-time definition n. a definition in the *compilation environment*.

compiled code n. 1. compiled functions. 2. code that represents compiled functions, such as the contents of a compiled file.

compiled file n. a file which represents the results of compiling the forms which appeared in a corresponding source file, and which can be loaded. See the function compile-file.

compiled function *n.* an *object* of *type* **compiled-function**, which is a *function* that has been *compiled*, which contains no references to *macros* that must be expanded at run time, and which contains no unresolved references to *load time values*.

compiler *n*. a facility that is part of Lisp and that translates *code* into an *implementation-dependent* form that might be represented or *executed* efficiently. The functions **compile** and **compile-file** permit programs to invoke the *compiler*.

compiler macro n. an auxiliary macro definition for a globally defined function or macro which might or might not be called by any given conforming implementation and which must preserve the semantics of the globally defined function or macro but which might perform some additional optimizations. (Unlike a macro, a compiler macro does not extend the syntax of Common Lisp; rather, it provides an alternate implementation strategy for some existing syntax or functionality.)

compiler macro expansion n. 1. the process of translating a *form* into another *form* by a *compiler macro*. 2. the *form* resulting from this process.

compiler macro form *n.* a function form or macro form whose operator has a definition as a compiler macro, or a **funcall** form whose first argument is a **function** form whose argument is the name of a function that has a definition as a compiler macro.

compiler macro function *n.* a function of two arguments, a form and an environment, that implements compiler macro expansion by producing either a form to be used in place of the original argument form or else **nil**, indicating that the original form should not be replaced. See Section 3.2.2.1 (Compiler Macros).

complex n. an object of type complex.

complex float n. an object of type **complex** which has a complex part type that is a subtype of **float**. A complex float is a complex, but it is not a float.

complex part type *n.* (of a *complex*) 1. the *type* which is used to represent both the real part and the imaginary part of the *complex*. 2. the *actual complex part type* of the *complex*. 3. the *expressed complex part type* of the *complex*.

complex rational *n.* an *object* of *type* **complex** which has a *complex part type* that is a *subtype* of **rational**. A *complex rational* is a *complex*, but it is not a *rational*. No *complex rational* has an imaginary part of zero because such a number is always represented by Common Lisp as an *object* of *type* **rational**; see Section 12.1.5.3 (Rule of Canonical Representation for Complex Rationals).

complex single float *n.* an *object* of *type* **complex** which has a *complex part type* that is a *subtype* of **single-float**. A *complex single float* is a *complex*, but it is not a *single float*.

composite stream *n.* a *stream* that is composed of one or more other *streams*. "make-synonym-stream creates a composite stream."

compound form n. a non-empty list which is a form: a special form, a lambda form, a macro form, or a function form.

compound type specifier *n.* a *type specifier* that is a *cons*; *i.e.*, a *type specifier* that is not an *atomic type specifier*. "(vector single-float) is a compound type specifier."

concatenated stream n. an input stream of type concatenated-stream.

condition n. 1. an object which represents a situation—usually, but not necessarily, during signaling. 2. an object of type condition.

condition designator *n.* one or more *objects* that, taken together, denote either an existing *condition object* or a *condition object* to be implicitly created. For details, see Section 9.1.2.1 (Condition Designators).

condition handler *n.* a function that might be invoked by the act of signaling, that receives the condition being signaled as its only argument, and that is permitted to handle the condition or to decline. See Section 9.1.4.1 (Signaling).

condition reporter *n.* a function that describes how a condition is to be printed when the Lisp printer is invoked while *print-escape* is false. See Section 9.1.3 (Printing Conditions).

conditional newline *n.* a point in output where a *newline* might be inserted at the discretion of the *pretty printer*. There are four kinds of *conditional newlines*, called "linear-style," "fill-style," "miser-style," and "mandatory-style." See the *function* **pprint-newline** and Section 22.2.1.1 (Dynamic Control of the Arrangement of Output).

conformance n. a state achieved by proper and complete adherence to the requirements of this specification. See Section 1.5 (Conformance).

conforming code *n. code* that is all of part of a *conforming program*.

conforming implementation n. an implementation, used to emphasize complete and correct adherance to all conformance criteria. A conforming implementation is

capable of accepting a conforming program as input, preparing that program for execution, and executing the prepared program in accordance with this specification. An implementation which has been extended may still be a conforming implementation provided that no extension interferes with the correct function of any conforming program.

conforming processor n. ANSI a conforming implementation.

conforming program *n.* a *program*, used to emphasize the fact that the *program* depends for its correctness only upon documented aspects of Common Lisp, and can therefore be expected to run correctly in any *conforming implementation*.

congruent *n.* conforming to the rules of *lambda list* congruency, as detailed in Section 7.6.4 (Congruent Lambda-lists for all Methods of a Generic Function).

cons n.v. 1. n. a compound data object having two components called the car and the cdr. 2. v. to create such an object. 3. v. Idiom. to create any object, or to allocate storage.

constant n. 1. a constant form. 2. a constant variable. 3. a constant object. 4. a self-evaluating object.

constant form n. any form for which evaluation always yields the same value, that neither affects nor is affected by the environment in which it is evaluated (except that it is permitted to refer to the names of constant variables defined in the environment), and that neither affects nor is affected by the state of any object except those objects that are otherwise inaccessible parts of objects created by the form itself. "A car form in which the argument is a quote form is a constant form."

constant object *n.* an *object* that is constrained (*e.g.*, by its context in a *program* or by the source from which it was obtained) to be *immutable*. "A literal object that has been processed by **compile-file** is a constant object."

constant variable n. a variable, the value of which can never change; that is, a $keyword_1$ or a $named\ constant$. "The symbols t, nil, :direction, and most-positive-fixnum are constant variables."

constituent n, adj. 1. a. n. the $syntax\ type$ of a character that is part of a token. For details, see Section 2.1.4.1 (Constituent Characters). b. adj. (of a character) having the $constituent_{1a}\ syntax\ type_2$. c. n. a $constituent_{1b}\ character$. 2. n. (of a $composite\ stream$) one of possibly several objects that collectively comprise the source or sink of that stream.

constituent trait n. (of a character) one of several classifications of a constituent character in a readtable. See Section 2.1.4.1 (Constituent Characters).

constructed stream *n.* a *stream* whose source or sink is a Lisp *object*. Note that since a *stream* is another Lisp *object*, *composite streams* are considered *constructed streams*. "A string stream is a constructed stream."

contagion n. a process whereby operations on objects of differing types (e.g., arithmetic on mixed types of numbers) produce a result whose type is controlled by the dominance of one argument's type over the types of the other arguments. See Section 12.1.1.2 (Contagion in Numeric Operations).

continuable n. (of an error) an error that is correctable by the continue restart.

control form n. 1. a form that establishes one or more places to which control can be transferred. 2. a form that transfers control.

copy n. 1. (of a $cons\ C$) a $fresh\ cons$ with the $same\ car$ and cdr as C. 2. (of a $list\ L$) a $fresh\ list$ with the $same\ elements$ as L. (Only the $list\ structure$ is fresh; the $elements\ are$ the same.) See the $function\ copy$ -list. 3. (of an $association\ list\ A$ with $elements\ A_i$) a $fresh\ list\ B$ with $elements\ B_i$, each of which is $nil\ if\ A_i$ is nil, or else a copy of the $cons\ A_i$. See the $function\ copy$ -alist. 4. (of a $tree\ T$) a $fresh\ tree\ with$ the $same\ leaves\ as\ T$. See the $function\ copy$ -tree. 5. (of a $random\ state\ R$) a $fresh\ random\ state\ that$, if used as an argument to to the $function\ random\ would\ produce$ the same series of "random" values as R would produce. 6. (of a $structure\ S$) a $fresh\ structure\ that\ has\ the\ same\ type\ as\ S$, and that has slot values, each of which is the $same\ as\ the\ corresponding\ slot\ value\ of\ S$. (Note that since the difference between a cons, a list, and a $tree\ is\ a\ matter\ of\ "view"\ or\ "intention,"\ there\ can\ be\ no\ general-purpose\ function\ which, based\ solely\ on\ the\ type\ of\ an\ object$, can determine which of these distinct meanings is intended. The distinction rests solely on the basis of the text description within this document. For\ example, phrases like "a copy of the given list" or "copy of the $list\ x$ " imply the second definition.)

correctable adj. (of an error) 1. (by a restart other than abort that has been associated with the error) capable of being corrected by invoking that restart. "The function cerror signals an error that is correctable by the continue restart." (Note that correctability is not a property of an error object, but rather a property of the dynamic environment that is in effect when the error is signaled. Specifically, the restart is "associated with" the error condition object. See Section 9.1.4.2.4 (Associating a Restart with a Condition).) 2. (when no specific restart is mentioned) $correctable_1$ by at least one restart. "import signals a correctable error of type package-error if any of the imported symbols has the same name as some distinct symbol already accessible in the package."

current input base n. (in a dynamic environment) the radix that is the value of *read-base* in that environment, and that is the default radix employed by the Lisp reader and its related functions.

current logical block n. the context of the innermost lexically enclosing use of **pprint-logical-block**.

current output base n. (in a dynamic environment) the radix that is the value of ***print-base*** in that environment, and that is the default radix employed by the Lisp printer and its related functions.

current package n. (in a dynamic environment) the package that is the value of ***package*** in that environment, and that is the default package employed by the Lisp reader and Lisp printer, and their related functions.

current pprint dispatch table n. (in a dynamic environment) the pprint dispatch table that is the value of *print-pprint-dispatch* in that environment, and that is the default pprint dispatch table employed by the pretty printer.

current random state n. (in a dynamic environment) the random state that is the value of *random-state* in that environment, and that is the default random state employed by random.

current readtable n. (in a dynamic environment) the readtable that is the value of *readtable* in that environment, and that affects the way in which expressions₂ are parsed into objects by the Lisp reader.

 \mathbf{D}

data type n. Trad. a type.

debug I/O n. the bidirectional stream that is the value of the variable *debug-io*.

debugger *n.* a facility that allows the *user* to handle a *condition* interactively. For example, the *debugger* might permit interactive selection of a *restart* from among the *active restarts*, and it might perform additional *implementation-defined* services for the purposes of debugging.

declaration *n.* a global declaration or local declaration.

declaration identifier n. one of the symbols declaration, dynamic-extent, ftype, function, ignore, inline, notinline, optimize, special, or type; or a symbol which is the name of a type; or a symbol which has been declared to be a declaration identifier by using a declaration declaration.

declaration specifier *n*. an *expression* that can appear at top level of a **declare** expression or a **declaim** form, or as the argument to **proclaim**, and which has a *car* which is a *declaration identifier*, and which has a *cdr* that is data interpreted according to rules specific to the *declaration identifier*.

declare v. to establish a declaration. See declare, declaim, or proclaim.

decline v. (of a handler) to return normally without having handled the condition being signaled, permitting the signaling process to continue as if the handler had not been present.

decoded time *n.* absolute time, represented as an ordered series of nine objects which, taken together, form a description of a point in calendar time, accurate to the nearest second (except that *leap seconds* are ignored). See Section 25.1.4.1 (Decoded Time).

default method n. a method having no parameter specializers other than the class **t**. Such a method is always an applicable method but might be shadowed₂ by a more specific method.

defaulted initialization argument list n. a list of alternating initialization argument names and values in which unsupplied initialization arguments are defaulted, used in the protocol for initializing and reinitializing instances of classes.

define-method-combination arguments lambda list n. a lambda list used by the :arguments option to define-method-combination. See Section 3.4.10 (Define-method-combination Arguments Lambda Lists).

define-modify-macro lambda list n. a lambda list used by define-modify-macro. See Section 3.4.9 (Define-modify-macro Lambda Lists).

defined name n. a symbol the meaning of which is defined by Common Lisp.

defining form *n.* a *form* that has the side-effect of *establishing* a definition. "**defun** and **defparameter** are defining forms."

defsetf lambda list n. a lambda list that is like an ordinary lambda list except that it does not permit &aux and that it permits use of &environment. See Section 3.4.7 (Defsetf Lambda Lists).

deftype lambda list n. a lambda list that is like a macro lambda list except that the default value for unsupplied optional parameters and keyword parameters is the symbol * (rather than nil). See Section 3.4.8 (Deftype Lambda Lists).

denormalized adj., ANSI, IEEE (of a float) conforming to the description of "denormalized" as described by IEEE Standard for Binary Floating-Point Arithmetic. For example, in an implementation where the minimum possible exponent was -7 but where 0.001 was a valid mantissa, the number 1.0e-10 might be representable as 0.001e-7 internally even if the normalized representation would call for it to be represented instead as 1.0e-10 or 0.1e-9. By their nature, denormalized floats generally have less precision than normalized floats.

derived type *n.* a *type specifier* which is defined in terms of an expansion into another *type specifier*. **deftype** defines *derived types*, and there may be other *implementation-defined operators* which do so as well.

derived type specifier *n.* a type specifier for a derived type.

designator *n.* an *object* that denotes another *object*. In the dictionary entry for an *operator* if a *parameter* is described as a *designator* for a *type*, the description of the *operator* is written in a way that assumes that appropriate coercion to that *type* has already occurred; that is, that the *parameter* is already of the denoted *type*. For more detailed information, see Section 1.4.1.5 (Designators).

destructive adj. (of an operator) capable of modifying some program-visible aspect of one or more objects that are either explicit arguments to the operator or that can be obtained directly or indirectly from the global environment by the operator.

destructuring lambda list *n.* an *extended lambda list* used in **destructuring-bind** and nested within *macro lambda lists*. See Section 3.4.5 (Destructuring Lambda Lists).

different adj. not the same "The strings "F00" and "foo" are different under equal but not under equalp."

digit n. (in a radix) a character that is among the possible digits (0 to 9, A to Z, and a to z) and that is defined to have an associated numeric weight as a digit in that radix. See Section 13.1.4.6 (Digits in a Radix).

dimension n. 1. a non-negative *integer* indicating the number of *objects* an *array* can hold along one axis. If the *array* is a *vector* with a *fill pointer*, the *fill pointer* is ignored. "The second dimension of that array is 7." 2. an axis of an array. "This array has six dimensions."

direct instance n. (of a $class\ C$) an object whose class is C itself, rather than some subclass of C. "The function **make-instance** always returns a direct instance of the class which is (or is named by) its first argument."

direct subclass n. (of a class C_1) a class C_2 , such that C_1 is a direct superclass of C_2 .

direct superclass n. (of a class C_1) a class C_2 which was explicitly designated as a superclass of C_1 in the definition of C_1 .

disestablish v.t. to withdraw the establishment of an object, a binding, an exit point, a taq, a handler, a restart, or an environment.

disjoint n. (of types) having no elements in common.

dispatching macro character *n.* a *macro character* that has an associated table that specifies the *function* to be called for each *character* that is seen following the *dispatching macro character*. See the *function* **make-dispatch-macro-character**.

displaced array *n.* an *array* which has no storage of its own, but which is instead indirected to the storage of another *array*, called its *target*, at a specified offset, in such a way that any attempt to *access* the *displaced array* implicitly references the *target array*.

distinct adj. not identical.

documentation string n. (in a defining form) A literal string which because of the context in which it appears (rather than because of some intrinsically observable aspect of the string) is taken as documentation. In some cases, the documentation string is saved in such a way that it can later be obtained by supplying either an object, or by supplying a name and a "kind" to the function **documentation**. "The body of code in a **defmacro** form can be preceded by a documentation string of kind function."

dot *n*. the *standard character* that is variously called "full stop," "period," or "dot" (.). See Figure 2–5.

dotted list *n.* a *list* which has a terminating *atom* that is not **nil**. (An *atom* by itself is not a *dotted list*, however.)

dotted pair n. 1. a cons whose cdr is a non-list. 2. any cons, used to emphasize the use of the cons as a symmetric data pair.

double float *n.* an *object* of *type* **double-float**.

double-quote n. the *standard character* that is variously called "quotation mark" or "double quote" ("). See Figure 2–5.

dynamic binding *n.* a binding in a dynamic environment.

dynamic environment n. that part of an environment that contains bindings with dynamic extent. A dynamic environment contains, among other things: exit points established by **unwind-protect**, and bindings of dynamic variables, exit points established by **catch**, condition handlers, and restarts.

dynamic extent *n.* an *extent* whose duration is bounded by points of *establishment* and *disestablishment* within the execution of a particular *form*. See *indefinite extent*. "Dynamic variable bindings have dynamic extent."

dynamic scope *n. indefinite scope* along with *dynamic extent*.

dynamic variable n. a variable the binding for which is in the dynamic environment. See special.

 \mathbf{E}

echo stream n. a stream of type echo-stream.

effective method *n*. the combination of *applicable methods* that are executed when a *generic function* is invoked with a particular sequence of *arguments*.

element n. 1. (of a list) an object that is the car of one of the conses that comprise the list. 2. (of an array) an object that is stored in the array. 3. (of a sequence) an object that is an element of the list or array that is the sequence. 4. (of a type) an object that is a member of the set of objects designated by the type. 5. (of an input stream) a character or number (as appropriate to the element type of the stream) that is among the ordered series of objects that can be read from the stream (using read-char or read-byte, as appropriate to the stream). 6. (of an output stream) a character or number (as appropriate to the element type of the stream) that is among the ordered series of objects that has been or will be written to the stream (using write-char or write-byte, as appropriate to the stream). 7. (of a class) a generalized instance of the class.

element type n. 1. (of an array) the array element type of the array. 2. (of a stream) the stream element type of the stream.

em n. Trad. a context-dependent unit of measure commonly used in typesetting, equal to the displayed width of of a letter "M" in the current font. (The letter "M" is traditionally chosen because it is typically represented by the widest glyph in the font, and other characters' widths are typically fractions of an em. In implementations providing non-Roman characters with wider characters than "M," it is permissible for another character to be the implementation-defined reference character for this measure, and for "M" to be only a fraction of an em wide.) In a fixed width font, a line with n characters is n ems wide; in a variable width font, n ems is the expected upper bound on the width of such a line.

empty list *n*. the *list* containing no *elements*. See ().

empty type n. the type that contains no elements, and that is a subtype of all types (including itself). See nil.

end of file n. 1. the point in an *input stream* beyond which there is no further data. Whether or not there is such a point on an *interactive stream* is *implementation-defined*. 2. a *situation* that occurs upon an attempt to obtain data from an *input stream* that is at the *end of file*₁.

environment n. 1. a set of *bindings*. See Section 3.1.1 (Introduction to Environments). 2. an *environment object*. "**macroexpand** takes an optional environment argument."

environment object n. an object representing a set of lexical bindings, used in the processing of a form to provide meanings for names within that form. "macroexpand takes an optional environment argument." (The object nil when used as an environment object denotes the null lexical environment; the values of environment parameters to macro functions are objects of implementation-dependent nature which represent the environment₁ in which the corresponding macro form is to be expanded.) See Section 3.1.1.4 (Environment Objects).

environment parameter n. A parameter in a defining form f for which there is no corresponding argument; instead, this parameter receives as its value an environment object which corresponds to the lexical environment in which the defining f appeared.

error n. 1. (only in the phrase "is an error") a *situation* in which the semantics of a program are not specified, and in which the consequences are undefined. 2. a *condition* which represents an *error situation*. See Section 1.4.2 (Error Terminology). 3. an *object* of *type* **error**.

error output n. the output stream which is the value of the dynamic variable *error-output*.

escape n., adj. 1. n. a single escape or a multiple escape. 2. adj. single escape or multiple escape.

establish v.t. to build or bring into being a binding, a declaration, an exit point, a tag, a handler, a restart, or an environment. "let establishes lexical bindings."

evaluate v.t. (a form or an implicit progn) to execute the code represented by the form (or the series of forms making up the implicit progn) by applying the rules of evaluation, returning zero or more values.

evaluation *n.* a model whereby *forms* are *executed*, returning zero or more values. Such execution might be implemented directly in one step by an interpreter or in two steps by first *compiling* the *form* and then *executing* the *compiled code*; this choice is dependent both on context and the nature of the *implementation*, but in any case is not in general detectable by any program. The evaluation model is designed in such a way that a *conforming implementation* might legitimately have only a compiler and no interpreter, or vice versa. See Section 3.1.2 (The Evaluation Model).

evaluation environment *n.* a *run-time environment* in which macro expanders and code specified by **eval-when** to be evaluated are evaluated. All evaluations initiated by the *compiler* take place in the *evaluation environment*.

execute v.t. Trad. (code) to perform the imperative actions represented by the code.

execution time *n*. the duration of time that *compiled code* is being *executed*.

exhaustive partition n. (of a type) a set of pairwise disjoint types that form an exhaustive union.

exhaustive union n. (of a type) a set of subtypes of the type, whose union contains all elements of that type.

exit point n. a point in a control form from which (e.g., block), through which (e.g., unwind-protect), or to which (e.q., tagbody) control and possibly values can be transferred both actively by using another control form and passively through the normal control and data flow of evaluation. "catch and block establish bindings for exit points to which throw and return-from, respectively, can transfer control and values; tagbody establishes a binding for an exit point with lexical extent to which go can transfer control; and unwind-protect establishes an exit point through which control might be transferred by operators such as throw, return-from, and go."

explicit return n. the act of transferring control (and possibly values) to a block by using return-from (or return).

explicit use n. (of a variable V in a form F) a reference to V that is directly apparent in the normal semantics of F; i.e., that does not expose any undocumented details of the macro expansion of the form itself. References to V exposed by expanding subforms of F are, however, considered to be explicit uses of V.

exponent marker n. a character that is used in the textual notation for a *float* to separate the mantissa from the exponent. The characters defined as exponent markers in the standard readtable are shown in Figure 26–1. For more information, see Section 2.1 (Character Syntax). "The exponent marker 'd' in '3.0d7' indicates that this number is to be represented as a double float."

Marker	Meaning
D or d	double-float
E or e	float (see *read-default-float-format*)
F or f	single-float
L or 1	long-float
s or s	short-float

Figure 26-1. Exponent Markers

export v.t. (a symbol in a package) to add the symbol to the list of external symbols of the package.

exported adj. (of a symbol in a package) being an external symbol of the package.

expressed adjustability n. (of an array) a generalized boolean that is conceptually (but not necessarily actually) associated with the array, representing whether the array is expressly adjustable. See also actual adjustability.

expressed array element type n. (of an array) the type which is the array element type implied by a type declaration for the array, or which is the requested array element type at its time of creation, prior to any selection of an upgraded array element type. (Common Lisp does not provide a way of detecting this type directly at run time, but an implementation is permitted to make assumptions about the array's contents and the operations which may be performed on the array when this type is noted during code analysis, even if those assumptions would not be valid in general for the upgraded array element type of the expressed array element type.)

expressed complex part type n. (of a complex) the type which is implied as the complex part type by a type declaration for the complex, or which is the requested complex part type at its time of creation, prior to any selection of an upgraded complex part type. (Common Lisp does not provide a way of detecting this type directly at run time, but an implementation is permitted to make assumptions about the operations which may be performed on the complex when this type is noted during code analysis, even if those assumptions would not be valid in general for the upgraded complex part type of the expressed complex part type.)

expression n. 1. an object, often used to emphasize the use of the object to encode or represent information in a specialized format, such as program text. "The second expression in a let form is a list of bindings." 2. the textual notation used to notate an object in a source file. "The expression 'sample is equivalent to (quote sample)."

expressly adjustable adj. (of an array) being actually adjustable by virtue of an explicit request for this characteristic having been made at the time of its creation. All arrays that are expressly adjustable are actually adjustable, but not necessarily vice versa.

extended character n. a character of type **extended-char**: a character that is not a base character.

extended function designator n. a designator for a function; that is, an object that denotes a function and that is one of: a function name (denoting the function it names in the global environment), or a function (denoting itself). The consequences are undefined if a function name is used as an extended function designator but it does not have a global definition as a function, or if it is a symbol that has a global definition as a macro or a special form. See also function designator.

extended lambda list n. a list resembling an ordinary lambda list in form and

purpose, but offering additional syntax or functionality not available in an *ordinary lambda list*. "defmacro uses extended lambda lists."

extension n. a facility in an *implementation* of Common Lisp that is not specified by this standard.

extent n. the interval of time during which a reference to an object, a binding, an exit point, a tag, a handler, a restart, or an environment is defined.

external file format n. an object of implementation-dependent nature which determines one of possibly several implementation-dependent ways in which characters are encoded externally in a character file.

external file format designator n. a designator for an external file format; that is, an object that denotes an external file format and that is one of: the symbol :default (denoting an implementation-dependent default external file format that can accommodate at least the base characters), some other object defined by the implementation to be an external file format designator (denoting an implementation-defined external file format), or some other object defined by the implementation to be an external file format (denoting itself).

external symbol n. (of a package) a symbol that is part of the 'external interface' to the package and that are inherited₃ by any other package that uses the package. When using the Lisp reader, if a package prefix is used, the name of an external symbol is separated from the package name by a single package marker while the name of an internal symbol is separated from the package name by a double package marker; see Section 2.3.4 (Symbols as Tokens).

externalizable object n. an object that can be used as a literal object in code to be processed by the file compiler.

 \mathbf{F}

false n. the symbol nil, used to represent the failure of a predicate test.

fbound [† **ef_lbaund**] adj. (of a function name) bound in the function namespace. (The names of macros and special operators are fbound, but the nature and type of the object which is their value is implementation-dependent. Further, defining a setf expander F does not cause the setf function (setf F) to become defined; as such, if there is a such a definition of a setf expander F, the function (setf F) can be fbound if and only if, by design or coincidence, a function binding for (setf F) has been independently established.) See the functions **fboundp** and **symbol-function**.

feature n. 1. an aspect or attribute of Common Lisp, of the *implementation*, or of the *environment*. 2. a *symbol* that names a *feature*₁. See Section 24.1.2 (Features). "The :ansi-cl feature is present in all conforming implementations."

feature expression n. A boolean combination of *features* used by the #+ and #reader macros in order to direct conditional reading of expressions by the Lisp
reader. See Section 24.1.2.1 (Feature Expressions).

features list *n*. the *list* that is the *value* of *features*.

file n. a named entry in a file system, having an implementation-defined nature.

file compiler n. any compiler which compiles source code contained in a file, producing a compiled file as output. The compile-file function is the only interface to such a compiler provided by Common Lisp, but there might be other, implementation-defined mechanisms for invoking the file compiler.

file position n. (in a stream) a non-negative integer that represents a position in the stream. Not all streams are able to represent the notion of file position; in the description of any operator which manipulates file positions, the behavior for streams that don't have this notion must be explicitly stated. For binary streams, the file position represents the number of preceding bytes in the stream. For character streams, the constraint is more relaxed: file positions must increase monotonically, the amount of the increase between file positions corresponding to any two successive characters in the stream is implementation-dependent.

file position designator n. (in a stream) a designator for a file position in that stream; that is, the symbol :start (denoting 0, the first file position in that stream), the symbol :end (denoting the last file position in that stream; i.e., the position following the last element of the stream), or a file position (denoting itself).

file stream n. an object of type file-stream.

file system n. a facility which permits aggregations of data to be stored in named files on some medium that is external to the $Lisp\ image$ and that therefore persists from session to session.

filename n. a handle, not necessarily ever directly represented as an object, that can be used to refer to a file in a file system. Pathnames and namestrings are two kinds of objects that substitute for filenames in Common Lisp.

fill pointer n. (of a vector) an integer associated with a vector that represents the index above which no elements are active. (A fill pointer is a non-negative integer no larger than the total number of elements in the vector. Not all vectors have fill pointers.)

finite adj. (of a type) having a finite number of elements. "The type specifier (integer 0 5) denotes a finite type, but the type specifiers integer and (integer 0) do not."

fixnum *n*. an *integer* of *type* **fixnum**.

float n. an object of type float.

for-value adj. (of a reference to a binding) being a reference that reads₁ the value of the binding.

form n. 1. any object meant to be evaluated. 2. a symbol, a compound form, or a self-evaluating object. 3. (for an operator, as in " $\langle\langle operator \rangle\rangle$ form") a compound form having that operator as its first element. "A quote form is a constant form."

formal argument n. Trad. a parameter.

formal parameter n. Trad. a parameter.

format v.t. (a format control and format arguments) to perform output as if by format, using the format string and format arguments.

format argument n. an object which is used as data by functions such as format which interpret format controls.

format control n. a format string, or a function that obeys the argument conventions for a function returned by the formatter macro. See Section 22.2.1.3 (Compiling Format Strings).

format directive n. 1. a sequence of characters in a format string which is introduced by a tilde, and which is specially interpreted by code which processes format strings to mean that some special operation should be performed, possibly involving data supplied by the format arguments that accompanied the format string. See the function format. "In "~D base 10 = ~8R", the character sequences '~D' and '~8R' are format directives." 2. the conceptual category of all format directives, which use the same dispatch character. "Both ""3d" and ""3,'0D" are valid uses of the '"D' format directive."

format string n. a string which can contain both ordinary text and format directives, and which is used in conjunction with format arguments to describe how text output should be formatted by certain functions, such as format.

free declaration n. a declaration that is not a bound declaration. See declare.

fresh adj. 1. (of an object yielded by a function) having been newly-allocated by that function. (The caller of a function that returns a fresh object may freely modify the object without fear that such modification will compromise the future correct behavior of that function.) 2. (of a binding for a name) newly-allocated; not shared with other bindings for that name.

freshline n. a conceptual operation on a *stream*, implemented by the *function* fresh-line and by the *format directive* ~&, which advances the display position to the beginning of the next line (as if a *newline* had been typed, or the *function* terpri had been called) unless the *stream* is already known to be positioned at the beginning of a line. Unlike *newline*, *freshline* is not a *character*.

funbound [**'efunbaund**] *n.* (of a function name) not fbound.

function n. 1. an object representing code, which can be called with zero or more arguments, and which produces zero or more values. 2. an object of type function.

function block name n. (of a function name) The symbol that would be used as the name of an implicit block which surrounds the body of a function having that function name. If the function name is a symbol, its function block name is the function name itself. If the function name is a list whose car is setf and whose cadr is a symbol, its function block name is the symbol that is the cadr of the function name. An implementation which supports additional kinds of function names must specify for each how the corresponding function block name is computed.

function cell n. Trad. (of a symbol) The place which holds the definition of the global function binding, if any, named by that symbol, and which is accessed by symbol-function. See cell.

function designator n. a designator for a function; that is, an object that denotes a function and that is one of: a symbol (denoting the function named by that symbol in the global environment), or a function (denoting itself). The consequences are undefined if a symbol is used as a function designator but it does not have a global definition as a function, or it has a global definition as a macro or a special form. See also extended function designator.

function form *n.* a *form* that is a *list* and that has a first element which is the *name* of a *function* to be called on *arguments* which are the result of *evaluating* subsequent elements of the *function form*.

function name n. 1. (in an environment) A symbol or a list (setf symbol) that is the name of a function in that environment. 2. A symbol or a list (setf symbol).

functional evaluation n. the process of extracting a functional value from a function name or a lambda expression. The evaluator performs functional evaluation implicitly when it encounters a function name or a lambda expression in the car of a compound form, or explicitly when it encounters a function special form. Neither a use of a symbol as a function designator nor a use of the function symbol-function to extract the functional value of a symbol is considered a functional evaluation.

functional value n. 1. (of a function name N in an environment E) The value of the binding named N in the function namespace for environment E; that is, the

contents of the function cell named N in environment E. 2. (of an fbound symbol S) the contents of the symbol's function cell; that is, the value of the binding named S in the function namespace of the global environment. (A name that is a macro name in the global environment or is a special operator might or might not be fbound. But if S is such a name and is fbound, the specific nature of its functional value is implementation-dependent; in particular, it might or might not be a function.)

further compilation *n. implementation-dependent* compilation beyond *minimal compilation*. Further compilation is permitted to take place at *run time*. "Block compilation and generation of machine-specific instructions are examples of further compilation."

 \mathbf{G}

general adj. (of an array) having $element\ type\ \mathbf{t}$, and consequently able to have any object as an element.

generalized boolean n. an *object* used as a truth value, where the symbol **nil** represents false and all other *objects* represent true. See boolean.

generalized instance n. (of a class) an object the class of which is either that class itself, or some subclass of that class. (Because of the correspondence between types and classes, the term "generalized instance of X" implies "object of type X" and in cases where X is a class (or $class\ name$) the reverse is also true. The former terminology emphasizes the view of X as a class while the latter emphasizes the view of X as a class while the latter emphasizes the view of x as a x

generalized reference *n.* a reference to a location storing an *object* as if to a *variable*. (Such a reference can be either to *read* or *write* the location.) See Section 5.1 (Generalized Reference). See also *place*.

generalized synonym stream n. (with a synonym stream symbol) 1. (to a stream) a synonym stream to the stream, or a composite stream which has as a target a generalized synonym stream to the stream. 2. (to a symbol) a synonym stream to the symbol, or a composite stream which has as a target a generalized synonym stream to the symbol.

generic function n. a function whose behavior depends on the classes or identities of the arguments supplied to it and whose parts include, among other things, a set of methods, a $lambda\ list$, and a $method\ combination\ type$.

generic function lambda list n. A lambda list that is used to describe data flow into a generic function. See Section 3.4.2 (Generic Function Lambda Lists).

gensym n. Trad. an uninterned symbol. See the function **gensym**.

global declaration *n.* a *form* that makes certain kinds of information about code globally available; that is, a **proclaim** *form* or a **declaim** *form*.

global environment n. that part of an *environment* that contains *bindings* with *indefinite scope* and *indefinite extent*.

global variable *n.* a *dynamic variable* or a *constant variable*.

glyph n. a visual representation. "Graphic characters have associated glyphs."

go v. to transfer control to a go point. See the special operator **go**.

go point one of possibly several *exit points* that are *established* by **tagbody** (or other abstractions, such as **prog**, which are built from **tagbody**).

go tag *n.* the *symbol* or *integer* that, within the *lexical scope* of a **tagbody** *form*, names an *exit point established* by that **tagbody** *form*.

graphic adj. (of a character) being a "printing" or "displayable" character that has a standard visual representation as a single glyph, such as A or * or =. Space is defined to be graphic. Of the standard characters, all but newline are graphic. See non-graphic.

 \mathbf{H}

handle v. (of a condition being signaled) to perform a non-local transfer of control, terminating the ongoing signaling of the condition.

handler n. a condition handler.

hash table n. an *object* of *type* **hash-table**, which provides a mapping from keys to values.

home package n. (of a symbol) the package, if any, which is contents of the package cell of the symbol, and which dictates how the Lisp printer prints the symbol when it is not accessible in the current package. (Symbols which have nil in their package cell are said to have no home package, and also to be apparently uninterned.)

Ι

I/O customization variable n. one of the stream variables in Figure 26–2, or some other (implementation-defined) stream variable that is defined by the implementation to be an I/O customization variable.

debug-io *error-io* *standard-input* *standard-output*	query-io* *trace-output*
-------------------------------------------------------------	--------------------------

Figure 26-2. Standardized I/O Customization Variables

identical adj. the same under eq.

identifier n. 1. a symbol used to identify or to distinguish names. 2. a string used the same way.

immutable adj. not subject to change, either because no operator is provided which is capable of effecting such change or because some constraint exists which prohibits the use of an operator that might otherwise be capable of effecting such a change. Except as explicitly indicated otherwise, implementations are not required to detect attempts to modify immutable objects or cells; the consequences of attempting to make such modification are undefined. "Numbers are immutable."

implementation n. a system, mechanism, or body of code that implements the semantics of Common Lisp.

implementation limit n. a restriction imposed by an *implementation*.

implementation-defined adj. implementation-dependent, but required by this specification to be defined by each conforming implementation and to be documented by the corresponding implementor.

implementation-dependent adj. describing a behavior or aspect of Common Lisp which has been deliberately left unspecified, that might be defined in some conforming implementations but not in others, and whose details may differ between implementations. A conforming implementation is encouraged (but not required) to document its treatment of each item in this specification which is marked implementation-dependent, although in some cases such documentation might simply identify the item as "undefined."

implementation-independent *adj.* used to identify or emphasize a behavior or aspect of Common Lisp which does not vary between *conforming implementations*.

implicit block n. a block introduced by a $macro\ form$ rather than by an explicit block form.

implicit compilation *n. compilation* performed during *evaluation*.

implicit progn n. an ordered set of adjacent forms appearing in another form, and defined by their context in that form to be executed as if within a **progn**.

implicit tagbody n. an ordered set of adjacent forms and/or tags appearing in another form, and defined by their context in that form to be executed as if within a **tagbody**.

import v.t. (a symbol into a package) to make the symbol be present in the package.

improper list n. a list which is not a proper list: a circular list or a dotted list.

inaccessible adj. not accessible.

 $indefinite\ extent\ n.$ an $extent\ whose\ duration\ is\ unlimited.$ "Most Common Lisp objects have indefinite extent."

indefinite scope *n. scope* that is unlimited.

indicator *n.* a property indicator.

indirect instance n. (of a class C_1) an object of class C_2 , where C_2 is a subclass of C_1 . "An integer is an indirect instance of the class number."

inherit v.t. 1. to receive or acquire a quality, trait, or characteristic; to gain access to a feature defined elsewhere. 2. (a class) to acquire the structure and behavior defined by a superclass. 3. (a package) to make symbols exported by another package accessible by using use-package.

initial pprint dispatch table *n.* the *value* of *print-pprint-dispatch* at the time the *Lisp image* is started.

initial readtable n. the value of *readtable* at the time the Lisp image is started.

initialization argument list n. a property list of initialization argument names and values used in the protocol for initializing and reinitializing instances of classes. See Section 7.1 (Object Creation and Initialization).

initialization form *n.* a *form* used to supply the initial *value* for a *slot* or *variable*. "The initialization form for a slot in a **defclass** form is introduced by the keyword :initform."

input adj. (of a stream) supporting input operations (i.e., being a "data source"). An input stream might also be an output stream, in which case it is sometimes called a bidirectional stream. See the function input-stream-p.

instance n. 1. a direct instance. 2. a generalized instance. 3. an indirect instance.

integer n. an object of type **integer**, which represents a mathematical integer.

interactive stream n. a stream on which it makes sense to perform interactive querying. See Section 21.1.1.1.3 (Interactive Streams).

intern v.t. 1. (a string in a package) to look up the string in the package, returning either a symbol with that name which was already accessible in the package or a newly created internal symbol of the package with that name. 2. Idiom. generally, to observe a protocol whereby objects which are equivalent or have equivalent names under some predicate defined by the protocol are mapped to a single canonical object.

internal symbol n. (of a package) a symbol which is accessible in the package, but which is not an external symbol of the package.

internal time n. time, represented as an integer number of internal time units. Absolute internal time is measured as an offset from an arbitrarily chosen, implementation-dependent base. See Section 25.1.4.3 (Internal Time).

internal time unit n. a unit of time equal to 1/n of a second, for some implementation-defined integer value of n. See the variable internal-time-units-per-second.

interned adj. Trad. 1. (of a symbol) accessible in any package. 2. (of a symbol in a specific package) present in that package.

interpreted function n. a function that is not a compiled function. (It is possible for there to be a conforming implementation which has no interpreted functions, but a conforming program must not assume that all functions are compiled functions.)

interpreted implementation n. an implementation that uses an execution strategy for interpreted functions that does not involve a one-time semantic analysis pre-pass, and instead uses "lazy" (and sometimes repetitious) semantic analysis of forms as they are encountered during execution.

interval designator n. (of $type\ T$) an ordered pair of objects that describe a subtypeof T by delimiting an interval on the real number line. See Section 12.1.6 (Interval Designators).

invalid n., adj. 1. n. a possible constituent trait of a character which if present signifies that the *character* cannot ever appear in a *token* except under the control of a single escape character. For details, see Section 2.1.4.1 (Constituent Characters). 2. adj. (of a character) being a character that has syntax type constituent in the current readtable and that has the constituent trait invalid₁. See Figure 2–8.

iteration form n. a compound form whose operator is named in Figure 26–3, or a compound form that has an implementation-defined operator and that is defined by the *implementation* to be an *iteration form*.

do	do-external-symbols	dotimes
do*	do-symbols	loop
do-all-symbols	dolist	

Figure 26–3. Standardized Iteration Forms

iteration variable n. a variable V, the binding for which was created by an explicit use of V in an iteration form.

 \mathbf{K}

key n. an object used for selection during retrieval. See association list, property list, and hash table. Also, see Section 17.1 (Sequence Concepts).

keyword n. 1. a symbol the home package of which is the KEYWORD package. 2. any symbol, usually but not necessarily in the KEYWORD package, that is used as an identifying marker in keyword-style argument passing. See lambda. 3. Idiom. a lambda list keyword.

keyword parameter n. A parameter for which a corresponding keyword argument is optional. (There is no such thing as a required keyword argument.) If the argument is not supplied, a default value is used. See also supplied-p parameter.

keyword/value pair *n.* two successive *elements* (a *keyword* and a *value*, respectively) of a *property list*.

 \mathbf{L}

lambda combination n. Trad. a lambda form.

lambda expression n. a list which can be used in place of a function name in certain contexts to denote a function by directly describing its behavior rather than indirectly by referring to the name of an established function; its name derives from the fact that its first element is the symbol lambda. See lambda.

lambda form n. a form that is a list and that has a first element which is a lambda expression representing a function to be called on arguments which are the result of evaluating subsequent elements of the lambda form.

lambda list n. a list that specifies a set of parameters (sometimes called lambda variables) and a protocol for receiving values for those parameters; that is, an ordinary lambda list, an extended lambda list, or a modified lambda list.

lambda list keyword n. a symbol whose name begins with ampersand and that is specially recognized in a lambda list. Note that no standardized lambda list keyword is in the KEYWORD package.

lambda variable n. a formal parameter, used to emphasize the variable's relation to the lambda list that established it.

leaf n. 1. an atom in a tree₁. 2. a terminal node of a tree₂.

leap seconds *n.* additional one-second intervals of time that are occasionally inserted into the true calendar by official timekeepers as a correction similar to "leap years." All Common Lisp *time* representations ignore *leap seconds*; every day is assumed to be exactly 86400 seconds long.

left-parenthesis *n.* the *standard character* "(", that is variously called "left parenthesis" or "open parenthesis" See Figure 2–5.

length n. (of a sequence) the number of elements in the sequence. (Note that if the sequence is a vector with a fill pointer, its length is the same as the fill pointer even though the total allocated size of the vector might be larger.)

lexical binding *n.* a binding in a lexical environment.

lexical closure n. a function that, when invoked on arguments, executes the body of a lambda expression in the lexical environment that was captured at the time of the creation of the lexical closure, augmented by bindings of the function's parameters to the corresponding arguments.

lexical environment n. that part of the *environment* that contains bindings whose names have *lexical scope*. A *lexical environment* contains, among other things: ordinary bindings of variable names to values, lexically established bindings of function names to functions, macros, symbol macros, blocks, tags, and local declarations (see declare).

lexical scope *n. scope* that is limited to a spatial or textual region within the establishing *form*. "The names of parameters to a function normally are lexically scoped."

lexical variable n. a variable the binding for which is in the lexical environment.

Lisp image n. a running instantiation of a Common Lisp implementation. A Lisp image is characterized by a single address space in which any object can directly refer to any another in conformance with this specification, and by a single, common, global environment. (External operating systems sometimes call this a "core image," "fork," "incarnation," "job," or "process." Note however, that the issue of a

"process" in such an operating system is technically orthogonal to the issue of a *Lisp image* being defined here. Depending on the operating system, a single "process" might have multiple *Lisp images*, and multiple "processes" might reside in a single *Lisp image*. Hence, it is the idea of a fully shared address space for direct reference among all *objects* which is the defining characteristic. Note, too, that two "processes" which have a communication area that permits the sharing of some but not all *objects* are considered to be distinct *Lisp images*.)

Lisp printer *n. Trad.* the procedure that prints the character representation of an *object* onto a *stream*. (This procedure is implemented by the *function* write.)

Lisp read-eval-print loop n. Trad. an endless loop that $reads_2$ a form, evaluates it, and prints $(i.e., writes_2)$ the results. In many implementations, the default mode of interaction with Common Lisp during program development is through such a loop.

Lisp reader *n. Trad.* the procedure that parses character representations of *objects* from a *stream*, producing *objects*. (This procedure is implemented by the *function* read.)

list n. 1. a chain of *conses* in which the *car* of each *cons* is an *element* of the *list*, and the *cdr* of each *cons* is either the next link in the chain or a terminating *atom*. See also *proper list*, *dotted list*, or *circular list*. 2. the *type* that is the union of **null** and **cons**.

list designator n. a designator for a list of objects; that is, an object that denotes a list and that is one of: a non-nil atom (denoting a singleton list whose element is that non-nil atom) or a proper list (denoting itself).

list structure n. (of a list) the set of conses that make up the list. Note that while the car_{1b} component of each such cons is part of the list structure, the objects that are elements of the list (i.e., the objects that are the $cars_2$ of each cons in the list) are not themselves part of its list structure, even if they are conses, except in the $(circular_2)$ case where the list actually contains one of its tails as an element. (The list structure of a list is sometimes redundantly referred to as its "top-level list structure" in order to emphasize that any conses that are elements of the list are not involved.)

literal adj. (of an object) referenced directly in a program rather than being computed by the program; that is, appearing as data in a **quote** form, or, if the object is a self-evaluating object, appearing as unquoted data. "In the form (cons "one" '("two")), the expressions "one", ("two"), and "two" are literal objects."

load v.t. (a file) to cause the code contained in the file to be executed. See the function load.

load time *n*. the duration of time that the loader is *loading compiled code*.

load time value n. an object referred to in code by a load-time-value form. The value of such a form is some specific object which can only be computed in the runtime environment. In the case of file compilation, the value is computed once as part of the process of loading the compiled file, and not again. See the special operator load-time-value.

loader n. a facility that is part of Lisp and that loads a file. See the function load.

local declaration n. an expression which may appear only in specially designated positions of certain forms, and which provides information about the code contained within the containing form; that is, a declare expression.

local precedence order n. (of a class) a list consisting of the class followed by its direct superclasses in the order mentioned in the defining form for the class.

local slot n. (of a class) a slot accessible in only one instance, namely the instance in which the *slot* is allocated.

logical block n. a conceptual grouping of related output used by the pretty printer. See the macro pprint-logical-block and Section 22.2.1.1 (Dynamic Control of the Arrangement of Output).

logical host n. an object of implementation-dependent nature that is used as the representation of a "host" in a logical pathname, and that has an associated set of translation rules for converting logical pathnames belonging to that host into physical pathnames. See Section 19.3 (Logical Pathnames).

logical host designator n. a designator for a logical host; that is, an object that denotes a logical host and that is one of: a string (denoting the logical host that it names), or a logical host (denoting itself). (Note that because the representation of a logical host is implementation-dependent, it is possible that an implementation might represent a *logical host* as the *string* that names it.)

logical pathname n. an object of type logical-pathname.

long float *n.* an *object* of *type* **long-float**.

loop keyword n. Trad. a symbol that is a specially recognized part of the syntax of an extended **loop** form. Such symbols are recognized by their name (using **string=**), not by their identity; as such, they may be in any package. A loop keyword is not a keyword.

lowercase adj. (of a character) being among standard characters corresponding to the small letters a through z, or being some other implementation-defined character that is defined by the implementation to be lowercase. See Section 13.1.4.3 (Characters With Case).

 \mathbf{M}

macro n. 1. a macro form 2. a macro function. 3. a macro name.

macro character n. a character which, when encountered by the Lisp reader in its main dispatch loop, introduces a reader $macro_1$. (Macro characters have nothing to do with macros.)

macro expansion n. 1. the process of translating a macro form into another form. 2. the form resulting from this process.

macro form n. a form that stands for another form (e.g., for the purposes of abstraction, information hiding, or syntactic convenience); that is, either a compound form whose first element is a macro name, or a form that is a symbol that names a symbol macro.

macro function *n.* a function of two arguments, a form and an environment, that implements macro expansion by producing a form to be evaluated in place of the original argument form.

macro lambda list n. an extended lambda list used in forms that establish macro definitions, such as defmacro and macrolet. See Section 3.4.4 (Macro Lambda Lists).

macro name n. a name for which **macro-function** returns true and which when used as the first element of a *compound form* identifies that form as a macro form.

macroexpand hook n. the function that is the value of *macroexpand-hook*.

mapping n. 1. a type of iteration in which a function is successively applied to objects taken from corresponding entries in collections such as sequences or hash tables. 2. Math. a relation between two sets in which each element of the first set (the "domain") is assigned one element of the second set (the "range").

metaclass n. 1. a class whose instances are classes. 2. (of an object) the class of the class of the object.

Metaobject Protocol *n*. one of many possible descriptions of how a *conforming implementation* might implement various aspects of the object system. This description is beyond the scope of this document, and no *conforming implementation* is required to adhere to it except as noted explicitly in this specification. Nevertheless,

its existence helps to establish normative practice, and implementors with no reason to diverge from it are encouraged to consider making their implementation adhere to it where possible. It is described in detail in The Art of the Metaobject Protocol.

method n. an object that is part of a generic function and which provides information about how that generic function should behave when its arguments are objects of certain classes or with certain identities.

method combination n. 1. generally, the composition of a set of methodsto produce an effective method for a generic function. 2. an object of type method-combination, which represents the details of how the method combination for one or more specific *generic functions* is to be performed.

method-defining form n. a form that defines a method for a generic function, whether explicitly or implicitly. See Section 7.6.1 (Introduction to Generic Functions).

method-defining operator n. an operator corresponding to a method-defining form. See Figure 7–1.

minimal compilation n. actions the compiler must take at compile time. See Section 3.2.2 (Compilation Semantics).

modified lambda list n. a list resembling an ordinary lambda list in form and purpose, but which deviates in syntax or functionality from the definition of an ordinary lambda list. See ordinary lambda list. "deftype uses a modified lambda list."

most recent adj. innermost; that is, having been established (and not yet disestab*lished*) more recently than any other of its kind.

multiple escape n., adj. 1. n. the syntax type of a character that is used in pairs to indicate that the enclosed *characters* are to be treated as *alphabetic*₂ *characters* with their case preserved. For details, see Section 2.1.4.5 (Multiple Escape Characters). 2. adj. (of a character) having the multiple escape syntax type. 3. n. a multiple escape₂ character. (In the standard readtable, vertical-bar is a multiple escape character.)

multiple values n. 1. more than one value. "The function truncate returns multiple values." 2. a variable number of values, possibly including zero or one. "The function values returns multiple values." 3. a fixed number of values other than one. "The macro multiple-value-bind is among the few operators in Common Lisp which can detect and manipulate multiple values."

 \mathbf{N}

name n., v.t. 1. n. an identifier by which an object, a binding, or an exit point is referred to by association using a binding. 2. v.t. to give a name to. 3. n. (of an object having a name component) the object which is that component. "The string which is a symbol's name is returned by symbol-name." 4. n. (of a pathname) a. the name component, returned by pathname-name. b. the entire namestring, returned by namestring. 5. n. (of a character) a string that names the character and that has length greater than one. (All non-graphic characters are required to have names unless they have some implementation-defined attribute which is not null. Whether or not other characters have names is implementation-dependent.)

named constant n. a variable that is defined by Common Lisp, by the implementation, or by user code (see the macro **defconstant**) to always yield the same value when evaluated. "The value of a named constant may not be changed by assignment or by binding."

namespace n. 1. bindings whose denotations are restricted to a particular kind. "The bindings of names to tags is the tag namespace." 2. any mapping whose domain is a set of names. "A package defines a namespace."

namestring n. a string that represents a filename using either the standardized notation for naming logical pathnames described in Section 19.3.1 (Syntax of Logical Pathname Namestrings), or some implementation-defined notation for naming a physical pathname.

newline n. the $standard\ character\ \langle Newline \rangle,\ notated\ for\ the\ Lisp\ reader$ as $\#\$ Newline.

next method n. the next method to be invoked with respect to a given method for a particular set of arguments or argument classes. See Section 7.6.6.1.3 (Applying method combination to the sorted list of applicable methods).

nickname n. (of a package) one of possibly several names that can be used to refer to the package but that is not the primary name of the package.

nil n. the object that is at once the symbol named "NIL" in the COMMON-LISP package, the empty list, the boolean (or generalized boolean) representing false, and the name of the empty type.

non-atomic adj. being other than an atom; i.e., being a cons.

non-constant variable *n.* a *variable* that is not a *constant variable*.

non-correctable adj. (of an error) not intentionally correctable. (Because of the dynamic nature of restarts, it is neither possible nor generally useful to completely prohibit an error from being correctable. This term is used in order to express an intent that no special effort should be made by code signaling an error to make that error correctable; however, there is no actual requirement on conforming programs or conforming implementations imposed by this term.)

non-empty adj. having at least one element.

non-generic function n. a function that is not a generic function.

non-graphic adj. (of a character) not graphic. See Section 13.1.4.1 (Graphic Characters).

non-list n., adj. other than a list; i.e., a non-nil atom.

non-local exit n. a transfer of control (and sometimes values) to an exit point for reasons other than a normal return. "The operators go, throw, and return-from cause a non-local exit."

non-nil n., adj. not nil. Technically, any object which is not nil can be referred to as true, but that would tend to imply a unique view of the object as a generalized boolean. Referring to such an object as non-nil avoids this implication.

non-null lexical environment n. a lexical environment that has additional information not present in the global environment, such as one or more bindings.

non-simple adj. not simple.

non-terminating adj. (of a macro character) being such that it is treated as a constituent character when it appears in the middle of an extended token. See Section 2.2 (Reader Algorithm).

non-top-level form n. a form that, by virtue of its position as a subform of another form, is not a top level form. See Section 3.2.3.1 (Processing of Top Level Forms).

normal return n. the natural transfer of control and values which occurs after the complete execution of a form.

normalized adj., ANSI, IEEE (of a float) conforming to the description of "normalized" as described by IEEE Standard for Binary Floating-Point Arithmetic. See denormalized.

null adj., n. 1. adj. a. (of a list) having no elements: empty. See empty list. b. (of a string) having a length of zero. (It is common, both within this document and

in observed spoken behavior, to refer to an empty string by an apparent definite reference, as in "the *null string*" even though no attempt is made to *intern*₂ null strings. The phrase "a *null string*" is technically more correct, but is generally considered awkward by most Lisp programmers. As such, the phrase "the *null string*" should be treated as an indefinite reference in all cases except for anaphoric references.) c. (of an *implementation-defined attribute* of a *character*) An *object* to which the value of that *attribute* defaults if no specific value was requested. 2. *n*. an *object* of *type* **null** (the only such *object* being **nil**).

null lexical environment *n.* the *lexical environment* which has no *bindings*.

number n. an object of type **number**.

numeric adj. (of a character) being one of the standard characters 0 through 9, or being some other graphic character defined by the implementation to be numeric.

 \mathbf{o}

object n. 1. any Lisp datum. "The function **cons** creates an object which refers to two other objects." 2. (immediately following the name of a type) an object which is of that type, used to emphasize that the object is not just a name for an object of that type but really an element of the type in cases where objects of that type (such as function or class) are commonly referred to by name. "The function symbol-function takes a function name and returns a function object."

object-traversing *adj.* operating in succession on components of an *object*. "The operators **mapcar**, **maphash**, **with-package-iterator** and **count** perform object-traversing operations."

open adj., v.t. (a file) 1. v.t. to create and return a stream to the file. 2. adj. (of a stream) having been $opened_1$, but not yet closed.

operator n. 1. a function, macro, or special operator. 2. a symbol that names such a function, macro, or special operator. 3. (in a function special form) the cadr of the function special form, which might be either an operator₂ or a lambda expression.

4. (of a compound form) the car of the compound form, which might be either an operator₂ or a lambda expression, and which is never (setf symbol).

optimize quality n. one of several aspects of a program that might be optimizable by certain compilers. Since optimizing one such quality might conflict with optimizing another, relative priorities for qualities can be established in an **optimize** declaration. The standardized optimize qualities are compilation-speed (speed of the compilation process), debug (ease of debugging), safety (run-time error checking), space (both code size and run-time space), and speed (of the object code). Implementations may define additional optimize qualities.

optional parameter n. A parameter for which a corresponding positional argument is optional. If the argument is not supplied, a default value is used. See also supplied-p parameter.

ordinary function n. a function that is not a generic function.

ordinary lambda list n. the kind of lambda list used by **lambda**. See modified lambda list and extended lambda list. "**defun** uses an ordinary lambda list."

otherwise inaccessible part n. (of an object, O_1) an object, O_2 , which would be made inaccessible if O_1 were made inaccessible. (Every object is an otherwise inaccessible part of itself.)

output adj. (of a stream) supporting output operations (i.e., being a "data sink"). An output stream might also be an input stream, in which case it is sometimes called a bidirectional stream. See the function **output-stream-p**.

P

package n. an object of type package.

package cell n. Trad. (of a symbol) The place in a symbol that holds one of possibly several packages in which the symbol is interned, called the home package, or which holds nil if no such package exists or is known. See the function symbol-package.

package designator n. a designator for a package; that is, an object that denotes a package and that is one of: a string designator (denoting the package that has the string that it designates as its name or as one of its nicknames), or a package (denoting itself).

package marker n. a character which is used in the textual notation for a symbol to separate the package name from the symbol name, and which is colon in the standard readtable. See Section 2.1 (Character Syntax).

package prefix n. a notation preceding the name of a symbol in text that is processed by the Lisp reader, which uses a package name followed by one or more package markers, and which indicates that the symbol is looked up in the indicated package.

package registry n. A mapping of names to package objects. It is possible for there to be a package object which is not in this mapping; such a package is called an unregistered package. Operators such as find-package consult this mapping in order to find a package from its name. Operators such as do-all-symbols, find-all-symbols, and list-all-packages operate only on packages that exist in the package registry.

pairwise adv. (of an adjective on a set) applying individually to all possible pairings of elements of the set. "The types A, B, and C are pairwise disjoint if A and B are disjoint, B and C are disjoint, and A and C are disjoint."

parallel adj. Trad. (of binding or assignment) done in the style of psetq, let, or do; that is, first evaluating all of the forms that produce values, and only then assigning or binding the variables (or places). Note that this does not imply traditional computational "parallelism" since the forms that produce values are evaluated sequentially. See sequential.

parameter n. 1. (of a function) a variable in the definition of a function which takes on the value of a corresponding argument (or of a list of corresponding arguments) to that function when it is called, or which in some cases is given a default value because there is no corresponding argument. 2. (of a format directive) an object received as data flow by a format directive due to a prefix notation within the format string at the format directive's point of use. See Section 22.3 (Formatted Output). "In "~3,'OD", the number 3 and the character #\0 are parameters to the ~D format directive."

parameter specializer n. 1. (of a method) an expression which constrains the method to be applicable only to argument sequences in which the corresponding argument matches the parameter specializer. 2. a class, or a list (eq1 object).

parameter specializer name n. 1. (of a method definition) an expression used in code to name a parameter specializer. See Section 7.6.2 (Introduction to Methods). 2. a class, a symbol naming a class, or a list (eq1 form).

pathname n. an object of type **pathname**, which is a structured representation of the name of a file. A pathname has six components: a "host," a "device," a "directory," a "name," a "type," and a "version."

pathname designator n. a designator for a pathname; that is, an object that denotes a pathname and that is one of: a pathname namestring (denoting the corresponding pathname), a stream associated with a file (denoting the pathname used to open the file; this may be, but is not required to be, the actual name of the file), or a pathname (denoting itself). See Section 21.1.1.1.2 (Open and Closed Streams).

physical pathname n. a pathname that is not a logical pathname.

place n. 1. a form which is suitable for use as a generalized reference. 2. the conceptual location referred to by such a $place_1$.

plist ['pē_llist] n. a property list.

portable adj. (of code) required to produce equivalent results and observable side effects in all conforming implementations.

potential copy n. (of an object O_1 subject to constriants) an object O_2 that if the specified constraints are satisfied by O_1 without any modification might or might not be identical to O_1 , or else that must be a fresh object that resembles a copy of O_1 except that it has been modified as necessary to satisfy the constraints.

potential number n. A textual notation that might be parsed by the *Lisp reader* in some *conforming implementation* as a *number* but is not required to be parsed as a *number*. No *object* is a *potential number*—either an *object* is a *number* or it is not. See Section 2.3.1.1 (Potential Numbers as Tokens).

pprint dispatch table n. an object that can be the value of *print-pprint-dispatch* and hence can control how objects are printed when *print-pretty* is true. See Section 22.2.1.4 (Pretty Print Dispatch Tables).

predicate n. a function that returns a generalized boolean as its first value.

present n. 1. (of a feature in a Lisp image) a state of being that is in effect if and only if the symbol naming the feature is an element of the features list. 2. (of a symbol in a package) being accessible in that package directly, rather than being inherited from another package.

pretty print v.t. (an object) to invoke the pretty printer on the object.

pretty printer *n*. the procedure that prints the character representation of an *object* onto a *stream* when the *value* of ***print-pretty*** is *true*, and that uses layout techniques (*e.g.*, indentation) that tend to highlight the structure of the *object* in a way that makes it easier for human readers to parse visually. See the *variable* ***print-print-dispatch*** and Section 22.2 (The Lisp Pretty Printer).

pretty printing stream n. a stream that does pretty printing. Such streams are created by the function **pprint-logical-block** as a link between the output stream and the logical block.

primary method n. a member of one of two sets of methods (the set of auxiliary methods is the other) that form an exhaustive partition of the set of methods on the method's generic function. How these sets are determined is dependent on the method combination type; see Section 7.6.2 (Introduction to Methods).

primary value n. (of values resulting from the evaluation of a form) the first value, if any, or else **nil** if there are no values. "The primary value returned by **truncate** is an integer quotient, truncated toward zero."

principal adj. (of a value returned by a Common Lisp function that implements a mathematically irrational or transcendental function defined in the complex domain)

of possibly many (sometimes an infinite number of) correct values for the mathematical function, being the particular *value* which the corresponding Common Lisp *function* has been defined to return.

print name n. Trad. (usually of a symbol) a name₃.

printer control variable n. a variable whose specific purpose is to control some action of the Lisp printer; that is, one of the variables in Figure 22–1, or else some implementation-defined variable which is defined by the implementation to be a printer control variable.

printer escaping *n*. The combined state of the *printer control variables* ***print-escape*** and ***print-readably***. If the value of either ***print-readably*** or ***print-escape*** is *true*, then *printer escaping* is "enabled"; otherwise (if the values of both ***print-readably*** and ***print-escape*** are *false*), then *printer escaping* is "disabled".

printing adj. (of a character) being a graphic character other than space.

process v.t. (a form by the compiler) to perform minimal compilation, determining the time of evaluation for a form, and possibly evaluating that form (if required).

processor n., ANSI an implementation.

proclaim v.t. (a proclamation) to establish that proclamation.

proclamation n. a global declaration.

prog tag n. Trad. a go tag.

program *n. Trad.* Common Lisp *code*.

programmer n. an active entity, typically a human, that writes a program, and that might or might not also be a user of the program.

programmer code n. code that is supplied by the programmer; that is, code that is not system code.

proper list n. A list terminated by the empty list. (The empty list is a proper list.) See improper list.

proper name n. (of a class) a symbol that names the class whose name is that symbol. See the functions class-name and find-class.

proper sequence n. a sequence which is not an improper list; that is, a vector or a proper list.

proper subtype n. (of a type) a subtype of the type which is not the same type as the type (i.e., its elements are a "proper subset" of the type).

property n. (of a property list) 1. a conceptual pairing of a property indicator and its associated property value on a property list. 2. a property value.

property indicator n. (of a property list) the name part of a property, used as a key when looking up a property value on a property list.

property list n. 1. a list containing an even number of elements that are alternating names (sometimes called indicators or keys) and values (sometimes called properties). When there is more than one name and value pair with the identical name in a property list, the first such pair determines the property. 2. (of a symbol) the component of the symbol containing a property list.

property value n. (of a property indicator on a property list) the object associated with the property indicator on the property list.

purports to conform v. makes a good-faith claim of conformance. This term expresses intention to conform, regardless of whether the goal of that intention is realized in practice. For example, language implementations have been known to have bugs, and while an *implementation* of this specification with bugs might not be a *conforming implementation*, it can still *purport to conform*. This is an important distinction in certain specific cases; e.g., see the variable *features*.

 \mathbf{Q}

qualified method *n.* a *method* that has one or more *qualifiers*.

qualifier n. (of a method for a generic function) one of possibly several objects used to annotate the method in a way that identifies its role in the method combination. The method combination type determines how many qualifiers are permitted for each method, which qualifiers are permitted, and the semantics of those qualifiers.

query I/O n. the bidirectional stream that is the value of the variable *query-io*.

quoted object *n.* an *object* which is the second element of a **quote** *form*.

 \mathbf{R}

radix n. an integer between 2 and 36, inclusive, which can be used to designate a base with respect to which certain kinds of numeric input or output are performed. (There are n valid digit characters for any given radix n, and those digits are the first n digits in the sequence 0, 1, ..., 9, A, B, ..., Z, which have the weights 0, 1, ..., 9, 10, 11, ..., 35, respectively. Case is not significant in parsing numbers of radix greater than 10, so "9b8a" and "9B8A" denote the same radix 16 number.)

random state n. an object of type random-state.

rank n. a non-negative integer indicating the number of dimensions of an array.

ratio n. an object of type ratio.

ratio marker n. a character which is used in the textual notation for a ratio to separate the numerator from the denominator, and which is slash in the standard readtable. See Section 2.1 (Character Syntax).

rational n. an object of type rational.

read v.t. 1. (a binding or slot or component) to obtain the value of the binding or slot. 2. (an object from a stream) to parse an object from its representation on the stream.

readably adv. (of a manner of printing an object O_1) in such a way as to permit the Lisp Reader to later parse the printed output into an object O_2 that is similar to O_1 .

reader n. 1. a function that $reads_1$ a variable or slot. 2. the Lisp reader.

reader macro n. 1. a textual notation introduced by dispatch on one or two characters that defines special-purpose syntax for use by the Lisp reader, and that is implemented by a reader macro function. See Section 2.2 (Reader Algorithm). 2. the character or characters that introduce a reader macro; that is, a macro character or the conceptual pairing of a dispatching macro character and the character that follows it. (A reader macro is not a kind of macro.)

reader macro function n. a function designator that denotes a function that implements a reader macro₂. See the functions set-macro-character and set-dispatch-macro-character.

readtable *n.* an *object* of *type* **readtable**.

readtable case n. an attribute of a readtable whose value is a case sensitivity mode, and that selects the manner in which characters in a symbol's name are to be treated

by the *Lisp reader* and the *Lisp printer*. See Section 23.1.2 (Effect of Readtable Case on the Lisp Reader) and Section 22.1.3.3.2 (Effect of Readtable Case on the Lisp Printer).

readtable designator n. a designator for a readtable; that is, an object that denotes a readtable and that is one of: **nil** (denoting the standard readtable), or a readtable (denoting itself).

recognizable subtype *n.* (of a *type*) a *subtype* of the *type* which can be reliably detected to be such by the *implementation*. See the *function* **subtypep**.

reference n., v.t. 1. n. an act or occurrence of referring to an object, a binding, an exit point, a tag, or an environment. 2. v.t. to refer to an object, a binding, an exit point, a tag, or an environment, usually by name.

registered package n. a package object that is installed in the package registry. (Every registered package has a name that is a string, as well as zero or more string nicknames. All packages that are initially specified by Common Lisp or created by make-package or defpackage are registered packages. Registered packages can be turned into unregistered packages by delete-package.)

relative adj. 1. (of a time) representing an offset from an absolute time in the units appropriate to that time. For example, a relative internal time is the difference between two absolute internal times, and is measured in internal time units. 2. (of a pathname) representing a position in a directory hierarchy by motion from a position other than the root, which might therefore vary. "The notation #P"../foo.text" denotes a relative pathname if the host file system is Unix." See absolute.

repertoire n., ISO a subtype of character. See Section 13.1.2.2 (Character Repertoires).

report n. (of a condition) to call the function **print-object** on the condition in an environment where the value of ***print-escape*** is false.

report message *n*. the text that is output by a *condition reporter*.

required parameter n. A parameter for which a corresponding positional argument must be supplied when calling the function.

rest list n. (of a function having a rest parameter) The list to which the rest parameter is bound on some particular call to the function.

rest parameter *n.* A *parameter* which was introduced by &rest.

restart *n*. an *object* of *type* **restart**.

restart designator n. a designator for a restart; that is, an object that denotes a restart and that is one of: a non-nil symbol (denoting the most recently established active restart whose name is that symbol), or a restart (denoting itself).

restart function n. a function that invokes a restart, as if by **invoke-restart**. The primary purpose of a restart function is to provide an alternate interface. By convention, a restart function usually has the same name as the restart which it invokes. Figure 26–4 shows a list of the standardized restart functions.

abort	muffle-warning	use-value	
continue	${f store-value}$		

Figure 26-4. Standardized Restart Functions

return v.t. (of values) 1. (from a block) to transfer control and values from the block; that is, to cause the block to yield the values immediately without doing any further evaluation of the forms in its body. 2. (from a form) to yield the values.

return value n. Trad. a $value_1$

right-parenthesis *n.* the *standard character* ")", that is variously called "right parenthesis" or "close parenthesis" See Figure 2–5.

run time n. 1. load time 2. execution time

run-time compiler n. refers to the compile function or to *implicit compilation*, for which the compilation and run-time *environments* are maintained in the same Lisp image.

run-time definition n. a definition in the run-time environment.

run-time environment n. the environment in which a program is executed.

 \mathbf{S}

safe adj. 1. (of code) processed in a lexical environment where the highest safety level (3) was in effect. See optimize. 2. (of a call) a safe call.

safe call n. a call in which the call, the function being called, and the point of functional evaluation are all $safe_1$ code. For more detailed information, see Section 3.5.1.1 (Safe and Unsafe Calls).

same adj. 1. (of objects under a specified predicate) indistinguishable by that predicate. "The symbol car, the string "car", and the string "CAR" are the same under

string-equal". 2. (of objects if no predicate is implied by context) indistinguishable by eql. Note that eq might be capable of distinguishing some numbers and characters which eql cannot distinguish, but the nature of such, if any, is implementationdependent. Since eq is used only rarely in this specification, eql is the default predicate when none is mentioned explicitly. "The conses returned by two successive calls to **cons** are never the same." 3. (of *types*) having the same set of *elements*; that is, each *type* is a *subtype* of the others. "The types specified by (integer 0 1), (unsigned-byte 1), and bit are the same."

satisfy the test v. (of an object being considered by a sequence function) 1. (for a one argument test) to be in a state such that the function which is the predicate argument to the sequence function returns true when given a single argument that is the result of calling the sequence function's key argument on the object being considered. See Section 17.2.2 (Satisfying a One-Argument Test). 2. (for a two arqument test) to be in a state such that the two-place predicate which is the sequence function's test argument returns true when given a first argument that is the object being considered, and when given a second argument that is the result of calling the sequence function's key argument on an element of the sequence function's sequence argument which is being tested for equality; or to be in a state such that the test-not function returns false given the same arguments. See Section 17.2.1 (Satisfying a Two-Argument Test).

scope n. the structural or textual region of code in which references to an object. a binding, an exit point, a tag, or an environment (usually by name) can occur.

script n. ISO one of possibly several sets that form an exhaustive partition of the type character. See Section 13.1.2.1 (Character Scripts).

secondary value n. (of values resulting from the evaluation of a form) the second value, if any, or else nil if there are fewer than two values. "The secondary value returned by **truncate** is a remainder."

section n. a partitioning of output by a conditional newline on a pretty printing stream. See Section 22.2.1.1 (Dynamic Control of the Arrangement of Output).

self-evaluating object n. an object that is neither a symbol nor a cons. If a selfevaluating object is evaluated, it yields itself as its only value. "Strings are selfevaluating objects."

semi-standard adj. (of a language feature) not required to be implemented by any conforming implementation, but nevertheless recommended as the canonical approach in situations where an *implementation* does plan to support such a feature. The presence of semi-standard aspects in the language is intended to lessen portability problems and reduce the risk of gratuitous divergence among implementations that might stand in the way of future standardization.

semicolon *n*. the *standard character* that is called "semicolon" (;). See Figure 2–5.

sequence n. 1. an ordered collection of elements 2. a vector or a list.

sequence function n one of the functions in Figure 17–1, or an implementation-defined function that operates on one or more sequences. and that is defined by the implementation to be a sequence function.

sequential adj. Trad. (of binding or assignment) done in the style of **setq**, let*, or **do***; that is, interleaving the evaluation of the forms that produce values with the assignments or bindings of the variables (or places). See parallel.

sequentially adv. in a sequential way.

serious condition *n.* a *condition* of *type* **serious-condition**, which represents a *situation* that is generally sufficiently severe that entry into the *debugger* should be expected if the *condition* is *signaled* but not *handled*.

session *n*. the conceptual aggregation of events in a *Lisp image* from the time it is started to the time it is terminated.

set v.t. Trad. (any variable or a symbol that is the name of a dynamic variable) to assign the variable.

setf expander n. a function used by **setf** to compute the *setf expansion* of a place.

setf expansion n. a set of five $expressions_1$ that, taken together, describe how to store into a *place* and which subforms of the macro call associated with the *place* are evaluated. See Section 5.1.1.2 (Setf Expansions).

setf function n. a function whose name is (setf symbol).

setf function name n. (of a symbol S) the list (setf S).

shadow v.t. 1. to override the meaning of. "That binding of X shadows an outer one." 2. to hide the presence of. "That macrolet of F shadows the outer flet of F." 3. to replace. "That package shadows the symbol cl:car with its own symbol car."

shadowing symbol n. (in a package) an element of the package's shadowing symbols list.

shadowing symbols list n. (of a package) a list, associated with the package, of symbols that are to be exempted from 'symbol conflict errors' detected when packages are used. See the function package-shadowing-symbols.

shared slot n. (of a class) a slot accessible in more than one instance of a class; specifically, such a slot is accessible in all direct instances of the class and in those indirect instances whose class does not shadow₁ the slot.

sharpsign n. the standard character that is variously called "number sign," "sharp," or "sharp sign" (#). See Figure 2–5.

short float *n*. an *object* of *type* **short-float**.

sign n. one of the standard characters "+" or "-".

signal v. to announce, using a standard protocol, that a particular situation, represented by a condition, has been detected. See Section 9.1 (Condition System Concepts).

signature n. (of a method) a description of the parameters and parameter specializers for the method which determines the method's applicability for a given set of required arguments, and which also describes the argument conventions for its other, non-required arguments.

similar adj. (of two objects) defined to be equivalent under the similarity relationship.

similarity n. a two-place conceptual equivalence predicate, which is independent of the Lisp image so that two objects in different Lisp images can be understood to be equivalent under this predicate. See Section 3.2.4 (Literal Objects in Compiled Files).

simple adj. 1. (of an array) being of type **simple-array**. 2. (of a character) having no implementation-defined attributes, or else having implementation-defined attributes each of which has the *null* value for that *attribute*.

simple array n. an array of type simple-array.

simple bit array n. a bit array that is a simple array; that is, an object of type (simple-array bit).

simple bit vector n. a bit vector of type simple-bit-vector.

simple condition n. a condition of type simple-condition.

simple general vector n. a simple vector.

simple string n. a string of type simple-string.

simple vector n. a vector of type **simple-vector**, sometimes called a "simple general vector." Not all vectors that are simple are simple vectors—only those that have element type **t**.

single escape n., adj. 1. n. the syntax type of a character that indicates that the next character is to be treated as an alphabetic₂ character with its case preserved. For details, see Section 2.1.4.6 (Single Escape Character). 2. adj. (of a character) having the single escape syntax type. 3. n. a single escape₂ character. (In the standard readtable, slash is the only single escape.)

single float n. an object of type single-float.

single-quote n. the *standard character* that is variously called "apostrophe," "acute accent," "quote," or "single quote" ('). See Figure 2–5.

singleton adj. (of a sequence) having only one element. "(list 'hello) returns a singleton list."

situation *n*. the *evaluation* of a *form* in a specific *environment*.

slash n. the *standard character* that is variously called "solidus" or "slash" (/). See Figure 2–5.

slot n. a component of an object that can store a value.

slot specifier *n.* a representation of a *slot* that includes the *name* of the *slot* and zero or more *slot* options. A *slot* option pertains only to a single *slot*.

source code *n. code* representing *objects* suitable for *evaluation* (*e.g.*, *objects* created by **read**, by *macro expansion*, or by *compiler macro expansion*).

source file n. a file which contains a textual representation of source code, that can be edited, loaded, or compiled.

space n. the standard character $\langle Space \rangle$, notated for the Lisp reader as #\Space.

special form n. a *list*, other than a *macro form*, which is a *form* with special syntax or special *evaluation* rules or both, possibly manipulating the *evaluation environment* or control flow or both. The first element of a *special form* is a *special operator*.

special operator n. one of a fixed set of symbols, enumerated in Figure 3–2, that may appear in the car of a form in order to identify the form as a special form.

special variable n. Trad. a dynamic variable.

specialize v.t. (a generic function) to define a method for the generic function, or in other words, to refine the behavior of the generic function by giving it a specific meaning for a particular set of classes or arguments.

specialized adj. 1. (of a generic function) having methods which specialize the generic function. 2. (of an array) having an actual array element type that is a proper subtype of the type t; see Section 15.1.1 (Array Elements). "(make-array 5 :element-type 'bit) makes an array of length five that is specialized for bits."

specialized lambda list *n.* an *extended lambda list* used in *forms* that *establish method* definitions, such as **defmethod**. See Section 3.4.3 (Specialized Lambda Lists).

spreadable argument list designator n. a designator for a list of objects; that is, an object that denotes a list and that is a non-null list L1 of length n, whose last element is a list L2 of length m (denoting a list L3 of length m+n-1 whose elements are $L1_i$ for i < n-1 followed by $L2_j$ for j < m). "The list $(1\ 2\ (3\ 4\ 5))$ is a spreadable argument list designator for the list $(1\ 2\ 3\ 4\ 5)$."

stack allocate v.t. Trad. to allocate in a non-permanent way, such as on a stack. Stack-allocation is an optimization technique used in some *implementations* for allocating certain kinds of *objects* that have *dynamic extent*. Such *objects* are allocated on the stack rather than in the heap so that their storage can be freed as part of unwinding the stack rather than taking up space in the heap until the next garbage collection. What types (if any) can have dynamic extent can vary from implementation to implementation. No implementation is ever required to perform stack-allocation.

stack-allocated adj. Trad. having been stack allocated.

standard character *n.* a *character* of *type* **standard-char**, which is one of a fixed set of 96 such *characters* required to be present in all *conforming implementations*. See Section 2.1.3 (Standard Characters).

standard class n. a class that is a generalized instance of class standard-class.

standard generic function a function of type standard-generic-function.

standard input *n*. the *input stream* which is the *value* of the *dynamic variable* *standard-input*.

standard method combination n. the method combination named standard.

 ${f standard\ object\ } n.$ an $object\ that$ is a $generalized\ instance$ of $class\ {f standard-object}.$

standard output n, the output stream which is the value of the dynamic variable *standard-output*.

standard pprint dispatch table n. A pprint dispatch table that is different from the initial pprint dispatch table, that implements pretty printing as described in this specification, and that, unlike other pprint dispatch tables, must never be modified by any program. (Although the definite reference "the standard pprint dispatch table" is generally used within this document, it is actually implementation-dependent whether a single object fills the role of the standard pprint dispatch table, or whether there might be multiple such objects, any one of which could be used on any given occasion where "the standard pprint dispatch table" is called for. As such, this phrase should be seen as an indefinite reference in all cases except for anaphoric references.)

standard readtable n. A readtable that is different from the initial readtable, that implements the expression syntax defined in this specification, and that, unlike other readtables, must never be modified by any program. (Although the definite reference "the standard readtable" is generally used within this document, it is actually implementation-dependent whether a single object fills the role of the standard readtable, or whether there might be multiple such objects, any one of which could be used on any given occasion where "the standard readtable" is called for. As such, this phrase should be seen as an indefinite reference in all cases except for anaphoric references.)

standard syntax n. the syntax represented by the *standard readtable* and used as a reference syntax throughout this document. See Section 2.1 (Character Syntax).

standardized adj. (of a name, object, or definition) having been defined by Common Lisp. "All standardized variables that are required to hold bidirectional streams have "-io*" in their name."

startup environment n. the global environment of the running Lisp image from which the compiler was invoked.

step v.t., n. 1. v.t. (an iteration variable) to assign the variable a new value at the end of an iteration, in preparation for a new iteration. 2. n. the code that identifies how the next value in an iteration is to be computed. 3. v.t. (code) to specially execute the code, pausing at intervals to allow user confirmation or intervention, usually for debugging.

stream n. an *object* that can be used with an input or output function to identify an appropriate source or sink of *characters* or *bytes* for that operation.

stream associated with a file n. a file stream, or a synonym stream the target of which is a stream associated with a file. Such a stream cannot be created with **make-two-way-stream**, **make-echo-stream**,

make-broadcast-stream, make-concatenated-stream, make-string-input-stream, or make-string-output-stream.

stream designator n. a designator for a stream; that is, an object that denotes a stream and that is one of: t (denoting the value of *terminal-io*), nil (denoting the value of *standard-input* for input stream designators or denoting the value of *standard-output* for output stream designators), or a stream (denoting itself).

stream element type n. (of a stream) the type of data for which the stream is specialized.

stream variable *n.* a *variable* whose *value* must be a *stream*.

stream variable designator n. a designator for a stream variable; that is, a symbol that denotes a stream variable and that is one of: t (denoting *terminal-io*), nil (denoting *standard-input* for input stream variable designators or denoting *standard-output* for output stream variable designators), or some other symbol (denoting itself).

string n. a specialized vector that is of type **string**, and whose elements are of type ${\bf character} \ {\rm or} \ {\rm a} \ {\it subtype} \ {\rm of} \ {\it type} \ {\bf character}.$

string designator n. a designator for a string; that is, an object that denotes a string and that is one of: a character (denoting a singleton string that has the character as its only element), a symbol (denoting the string that is its name), or a string (denoting itself). The intent is that this term be consistent with the behavior of string; implementations that extend string must extend the meaning of this term in a compatible way.

string equal adj. the same under string-equal.

string stream n. a stream of type string-stream.

structure n. an object of type structure-object.

structure class n. a class that is a generalized instance of class structure-class.

structure name n. a name defined with **defstruct**. Usually, such a type is also a structure class, but there may be implementation-dependent situations in which this is not so, if the :type option to defstruct is used.

style warning *n*. a condition of type style-warning.

subclass n. a class that inherits from another class, called a superclass. (No class is a *subclass* of itself.)

subexpression n. (of an expression) an expression that is contained within the expression. (In fact, the state of being a subexpression is not an attribute of the subexpression, but really an attribute of the containing expression since the same object can at once be a subexpression in one context, and not in another.)

subform n. (of a form) an expression that is a subexpression of the form, and which by virtue of its position in that form is also a form. "(f x) and x, but not exit, are subforms of (return-from exit (f x))."

subrepertoire *n.* a subset of a *repertoire*.

subtype n. a type whose membership is the same as or a proper subset of the membership of another type, called a supertype. (Every type is a subtype of itself.)

superclass n. a class from which another class (called a subclass) inherits. (No class is a superclass of itself.) See subclass.

supertype n. a type whose membership is the same as or a proper superset of the membership of another type, called a subtype. (Every type is a supertype of itself.) See subtype.

supplied-p parameter n. a parameter which receives its generalized boolean value implicitly due to the presence or absence of an argument corresponding to another parameter (such as an optional parameter or a rest parameter). See Section 3.4.1 (Ordinary Lambda Lists).

symbol n. an object of type symbol.

symbol macro n. a symbol that stands for another form. See the macro symbol-macrolet.

synonym stream n. 1. a stream of type **synonym-stream**, which is consequently a stream that is an alias for another stream, which is the value of a dynamic variable whose name is the synonym stream symbol of the synonym stream. See the function **make-synonym-stream**. 2. (to a stream) a synonym stream which has the stream as the value of its synonym stream symbol. 3. (to a symbol) a synonym stream which has the symbol as its synonym stream symbol.

synonym stream symbol n. (of a synonym stream) the symbol which names the dynamic variable which has as its value another stream for which the synonym stream is an alias.

syntax type n. (of a *character*) one of several classifications, enumerated in Figure 2–6, that are used for dispatch during parsing by the *Lisp reader*. See Section 2.1.4 (Character Syntax Types).

system class n. a class that may be of type **built-in-class** in a conforming implementation and hence cannot be inherited by classes defined by conforming programs.

system code *n. code* supplied by the *implementation* to implement this specification (*e.g.*, the definition of **mapcar**) or generated automatically in support of this specification (*e.g.*, during method combination); that is, *code* that is not *programmer code*.

 \mathbf{T}

t n. 1. a. the boolean representing true. b. the canonical generalized boolean representing true. (Although any object other than nil is considered true as a generalized boolean, t is generally used when there is no special reason to prefer one such object over another.) 2. the name of the type to which all objects belong—the supertype of all types (including itself). 3. the name of the superclass of all classes except itself.

tag n. 1. a catch tag. 2. a go tag.

tail n. (of a list) an object that is the same as either some cons which makes up that list or the atom (if any) which terminates the list. "The empty list is a tail of every proper list."

target n. 1. (of a constructed stream) a constituent of the constructed stream. "The target of a synonym stream is the value of its synonym stream symbol." 2. (of a displaced array) the array to which the displaced array is displaced. (In the case of a chain of constructed streams or displaced arrays, the unqualified term "target" always refers to the immediate target of the first item in the chain, not the immediate target of the last item.)

terminal I/O *n*. the *bidirectional stream* that is the *value* of the *variable* *terminal-io*.

terminating *n.* (of a *macro character*) being such that, if it appears while parsing a token, it terminates that token. See Section 2.2 (Reader Algorithm).

tertiary value n. (of values resulting from the evaluation of a form) the third value, if any, or else **nil** if there are fewer than three values.

throw v. to transfer control and values to a catch. See the special operator throw.

tilde n. the standard character that is called "tilde" (~). See Figure 2–5.

time a representation of a point (absolute time) or an interval (relative time) on a time line. See decoded time, internal time, and universal time.

time zone n. a rational multiple of 1/3600 between -24 (inclusive) and 24 (inclusive) that represents a time zone as a number of hours offset from Greenwich Mean Time. Time zone values increase with motion to the west, so Massachusetts, U.S.A. is in time zone 5, California, U.S.A. is time zone 8, and Moscow, Russia is time zone -3. (When "daylight savings time" is separately represented as an argument or return value, the time zone that accompanies it does not depend on whether daylight savings time is in effect.)

token n. a textual representation for a number or a symbol. See Section 2.3 (Interpretation of Tokens).

top level form n. a form which is processed specially by compile-file for the purposes of enabling compile time evaluation of that form. Top level forms include those forms which are not subforms of any other form, and certain other cases. See Section 3.2.3.1 (Processing of Top Level Forms).

trace output n. the output stream which is the value of the dynamic variable *trace-output*.

tree n. 1. a binary recursive data structure made up of conses and atoms: the conses are themselves also trees (sometimes called "subtrees" or "branches"), and the atoms are terminal nodes (sometimes called leaves). Typically, the leaves represent data while the branches establish some relationship among that data. 2. in general, any recursive data structure that has some notion of "branches" and leaves.

tree structure n. (of a $tree_1$) the set of conses that make up the tree. Note that while the car_{1b} component of each such cons is part of the tree structure, the objects that are the $cars_2$ of each cons in the tree are not themselves part of its tree structure unless they are also conses.

true n. any *object* that is not *false* and that is used to represent the success of a *predicate* test. See t_1 .

truename n. 1. the canonical filename of a file in the file system. See Section 20.1.3 (Truenames). 2. a pathname representing a truename₁.

two-way stream *n.* a *stream* of *type* **two-way-stream**, which is a *bidirectional composite stream* that receives its input from an associated *input stream* and sends its output to an associated *output stream*.

type n. 1. a set of *objects*, usually with common structure, behavior, or purpose. (Note that the expression "X is of type S_a " naturally implies that "X is of type S_b " if S_a is a *subtype* of S_b .) 2. (immediately following the name of a *type*) a *subtype* of that type. "The type **vector** is an array type."

type declaration n. a declaration that asserts that every reference to a specified binding within the scope of the declaration results in some object of the specified type.

type equivalent adj. (of two $types\ X$ and Y) having the same elements; that is, X is a subtype of Y and Y is a subtype of X.

type expand n. to fully expand a type specifier, removing any references to derived types. (Common Lisp provides no program interface to cause this to occur, but the semantics of Common Lisp are such that every implementation must be able to do this internally, and some situations involving type specifiers are most easily described in terms of a fully expanded type specifier.)

type specifier n. an expression that denotes a type. "The symbol random-state, the list (integer 3 5), the list (and list (not null)), and the class named standard-class are type specifiers."

 \mathbf{U}

unbound adj. not having an associated denotation in a binding. See bound.

unbound variable *n*. a *name* that is syntactically plausible as the name of a *variable* but which is not *bound* in the *variable namespace*.

undefined function n. a name that is syntactically plausible as the name of a function but which is not bound in the function namespace.

unintern v.t. (a symbol in a package) to make the symbol not be present in that package. (The symbol might continue to be accessible by inheritance.)

uninterned adj. (of a symbol) not accessible in any package; i.e., not interned₁.

universal time *n. time*, represented as a non-negative *integer* number of seconds. *Absolute universal time* is measured as an offset from the beginning of the year 1900 (ignoring *leap seconds*). See Section 25.1.4.2 (Universal Time).

unqualified method *n.* a *method* with no *qualifiers*.

unregistered package n. a package object that is not present in the package registry. An unregistered package has no name; i.e., its name is **nil**. See the function **delete-package**.

unsafe adj. (of code) not safe. (Note that, unless explicitly specified otherwise, if a particular kind of error checking is guaranteed only in a safe context, the same

checking might or might not occur in that context if it were *unsafe*; describing a context as *unsafe* means that certain kinds of error checking are not reliably enabled but does not guarantee that error checking is definitely disabled.)

unsafe call n. a call that is not a $safe\ call$. For more detailed information, see Section 3.5.1.1 (Safe and Unsafe Calls).

upgrade v.t. (a declared type to an actual type) 1. (when creating an array) to substitute an actual array element type for an expressed array element type when choosing an appropriately specialized array representation. See the function **upgraded-array-element-type**. 2. (when creating a complex) to substitute an actual complex part type for an expressed complex part type when choosing an appropriately specialized complex representation. See the function **upgraded-complex-part-type**.

upgraded array element type *n.* (of a *type*) a *type* that is a *supertype* of the *type* and that is used instead of the *type* whenever the *type* is used as an *array element type* for object creation or type discrimination. See Section 15.1.2.1 (Array Upgrading).

upgraded complex part type n. (of a type) a type that is a supertype of the type and that is used instead of the type whenever the type is used as a $complex\ part\ type$ for object creation or type discrimination. See the function **upgraded-complex-part-type**.

uppercase adj. (of a character) being among standard characters corresponding to the capital letters A through Z, or being some other implementation-defined character that is defined by the implementation to be uppercase. See Section 13.1.4.3 (Characters With Case).

use v.t. (a package P_1) to inherit the external symbols of P_1 . (If a package P_2 uses P_1 , the external symbols of P_1 become internal symbols of P_2 unless they are explicitly exported.) "The package CL-USER uses the package CL."

use list n. (of a package) a (possibly empty) list associated with each package which determines what other packages are currently being used by that package.

user n. an active entity, typically a human, that invokes or interacts with a program at run time, but that is not necessarily a programmer.

 \mathbf{V}

valid array dimension n. a fixnum suitable for use as an array dimension. Such a fixnum must be greater than or equal to zero, and less than the value of array-dimension-limit. When multiple array dimensions are to be used together to specify a multi-dimensional array, there is also an implied constraint that the product of all of the dimensions be less than the value of array-total-size-limit.

valid array index n. (of an array) a fixnum suitable for use as one of possibly several indices needed to name an element of the array according to a multi-dimensional Cartesian coordinate system. Such a fixnum must be greater than or equal to zero, and must be less than the corresponding dimension of the array. (Unless otherwise explicitly specified, the phrase "a list of valid array indices" further implies that the length of the list must be the same as the rank of the array.) "For a 2 by 3 array, valid array indices for the first dimension are 0 and 1, and valid array indices for the second dimension are 0, 1 and 2."

valid array row-major index n. (of an array, which might have any number of dimensions₂) a single fixnum suitable for use in naming any element of the array, by viewing the array's storage as a linear series of elements in row-major order. Such a fixnum must be greater than or equal to zero, and less than the array total size of the array.

valid fill pointer n. (of an array) a fixnum suitable for use as a fill pointer for the array. Such a fixnum must be greater than or equal to zero, and less than or equal to the array total size of the array.

valid logical pathname host n. a string that has been defined as the name of a logical host. See the function load-logical-pathname-translations.

valid pathname device n. a string, nil, :unspecific, or some other object defined by the implementation to be a valid pathname device.

valid pathname directory n. a string, a list of strings, nil, :wild, :unspecific, or some other object defined by the implementation to be a valid directory component.

valid pathname host n. a valid physical pathname host or a valid logical pathname host.

valid pathname name n. a string, nil, :wild, :unspecific, or some other object defined by the *implementation* to be a valid pathname name.

valid pathname type n. a string, nil, :wild, :unspecific.

valid pathname version n. a non-negative integer, or one of :wild, :newest, :unspecific, or nil. The symbols :oldest, :previous, and :installed are semistandard special version symbols.

valid physical pathname host n. any of a string, a list of strings, or the symbol :unspecific, that is recognized by the implementation as the name of a host.

valid sequence index n. (of a sequence) an integer suitable for use to name an element of the sequence. Such an integer must be greater than or equal to zero, and must be less than the *length* of the *sequence*. (If the *sequence* is an *array*, the *valid* sequence index is further constrained to be a *fixnum*.)

value n. 1. a. one of possibly several objects that are the result of an evaluation. b. (in a situation where exactly one value is expected from the evaluation of a form) the primary value returned by the form. c. (of forms in an implicit progn) one of possibly several objects that result from the evaluation of the last form, or nil if there are no forms. 2. an object associated with a name in a binding. 3. (of a symbol) the value of the dynamic variable named by that symbol. 4. an object associated with a key in an association list, a property list, or a hash table.

value cell n. Trad. (of a symbol) The place which holds the value, if any, of the dynamic variable named by that symbol, and which is accessed by **symbol-value**. See cell.

variable n. a binding in the "variable" namespace. See Section 3.1.2.1.1 (Symbols as Forms).

vector n. a one-dimensional array.

vertical-bar n. the *standard character* that is called "vertical bar" (1). See Figure 2–5.

W

whitespace n. 1. one or more characters that are either the graphic character #\Space or else non-graphic characters such as #\Newline that only move the print position. 2. a. n. the syntax type of a character that is a token separator. For details, see Section 2.1.4.7 (Whitespace Characters). b. adj. (of a character) having the whitespace_{2a} syntax type₂. c. n. a whitespace_{2b} character.

wild adj. 1. (of a namestring) using an implementation-defined syntax for naming files, which might "match" any of possibly several possible filenames, and which can therefore be used to refer to the aggregate of the files named by those filenames. 2. (of a pathname) a structured representation of a name which might "match" any of possibly several pathnames, and which can therefore be used to refer to the aggregate of the files named by those pathnames. The set of wild pathnames includes, but is not restricted to, pathnames which have a component which is :wild, or which have a directory component which contains :wild or :wild-inferors. See the function wild-pathname-p.

write v.t. 1. (a binding or slot or component) to change the value of the binding or slot. 2. (an object to a stream) to output a representation of the object to the stream.

writer n. a function that writes₁ a variable or slot.

 ${f Y}$

 $\mathbf{yield}\ v.t.\ (values)$ to produce the values as the result of evaluation. "The form (+ 2 3) yields 5."
